90. Several cases of very protracted phthisis have come under my notice, several of them in medical men. Dr. T. was attacked by hemoptysis at the age of 20 when studying in Edinburgh. His circumstances having admitted of his relinquishing practice soon after entering upon it, and having experienced returns of the hemorrage, with other pectoral symptoms, he travelled or voyaged to several parts in the West Indies, and in the south of Europe, generally passing a part of the year in one or other of these, and returning to England in the summer. Nevertheless his phthisical symptoms never left him, were exacerbatet after considerable intervals, and the hemoptysis also returned, and was sometimes alarming. This state of health continued for many years, and he continued to pass his winters in some mild climate, most frequently in that in which he found in the habit of being in the west of France. When the age of 57 or 58 he first called upon me, told me his case, and informed me that he had consulted all the consumption doctors, and that they were almost equally divided as to the existence or non-existence of cavities. I told him, after a careful examination, that there were cavities in both lungs, but that they were small, and that they most probably were filled up by the accumulated morbid secretions for a considerable time, and thus they escaped detection. He continued under my care for several years, during the periods of his residence in London or its vicinity. But the attacks of hemoptysis were more frequent, so much so ultimately that he always carried with him pills consisting of the ergot of rye, and a bottle of turpentine. He took the former as soon as the hemorrage appeared, and if that failed, he had recourse, as I had directed, to the turpentine. These means generally succeeded, but the other pulmonary symptoms gradually advanced. When about the age of 67, he was seized with hemoptysis when getting out of a railway-carriage at Paddington, had recourse to his usual remedies, and sent for me.

91. Before I reached his residence he was dead, suffocated by the hemoptysis. The body was inspected the following day. Several cavities were found in both lungs. None of them was large. The smaller were apparently contracted; their parietes were smooth, fibro-serous, and almost fibro-cartilaginous in parts; and one or two of them so much reduced as to be almost cicatrised; the parietes being quite smooth and fibro-cartilaginous. The surrounding tissues were condensed. Some of the cavities had a membranous parietes, whilst in others the walls consisted of a somewhat condensed pulmonic tissue, with minute openings, chiefly venous or bronchial. The cavities were all filled with blood, as were also the larger bronchi, and contained but little mucopurulent matter. This case had evidently been of forty-four years' duration; and it presented appearances, as respected the cavities, of the longest and shortest duration.*

92. E. Phthisis in Infants and Children occurs chiefly in the serofulous diathesis, as a consequence of an undiagnosed disorder of the digestive and assimilating functions, which in children may generate both the serofulous diathesis and tubercular disease. Disorder of these functions may in all temperaments so affect the circulating fluids as to develop that habit of body, in early life, which constitutes the serofulous diathesis, and which, in its more manifest states, implicates not merely the lungs, but other organs also. When treating of Serofula and Tubercles, I have shown that the serofulous diathesis may either be inherited or generated by the parent, and by the offspring in childhood, by causes which depress or exhaust organic nervous power—impaired digestion and assimilation of the huminatose, and imperfect nutrition resulting therefrom—and thus engraving serofula and tuberculous upon any temperament. It is therefore most important that this disorder of the digestive and assimilating functions in childhood should be recognised and traced to its causes, and that these causes should be removed.

93. The aspect of children thus affected suggests the idea of imperfect organic power. The child is languid, feeble. At the flesh of the limbs, the skin harsh, dry, and unhealthy to the sight and touch. It is disinclined to play or to active exertions.

* Dr. W. H., who had been Editor of the "London Medical and Physical Journal" in the years 1819, 1829, and 1831, in 1823 evinced indications of pulmonary disease, and in the following year he had a most severe attack of hemoptysis. He came under my care, and I advised him to pass the following winter at Naples. He returned to England in June, but was more or less of an invalid all the summer and autumn. He went to the coast of Devonshire the next winter; and he thus continued to change his place of residence for many years, often returning to London or its vicinity during portions of the summer and autumn. The pulmonary symptoms were sometimes slight, at other times severe. He died about 20 years after his first attack, in the vicinity of London. The treatment of this case, and of Dr. W.'s, was conformable with that which I shall have to recommend in the sequel. Miss L. came under my care about nine years ago, in the third stage of phthisis. The symptoms and sign of cavities in the lungs had previously been recognized by the physician whom she had previously consulted. When I saw her these were unmistakable. During the years which have intervened since my first visit, she has experienced intermittent attacks of bronchitis, partial pleuritis, &c., which have been successively overcome; and during the severe winter and spring of last year she was confined a day to her apartment, but barely to the house. The physical signs and chief symptoms of cavities in the lungs still exist. It is not to adduce numerous other instances of the protracted form of this disease, if it were necessary to do so.
TUBERCULAR CONSUMPTION — IN THE DARK RACES. 1107

The face is pale, or pasty, or faded. The eyes appear large; the pupils are dilated, and the conjunctiva white. The tongue is whitish, and dotted with small red points, the extremity and sides being red, and the root and centre loaded, or more or less furred, especially in the morning. The appetite is variable, often craving or unnatural; thirst is not infrequent; and the breath is fetid. The bowels are irregular, most frequently constive, but sometimes very loose; and the evacuations are offensive, often pale, greyish or clayey; occasionally mucus and imperfectly digested food are observed in the stools. The urine is either high-coloured at times, scanty or abundant, turbid or pale. The extremities are usually cold, and sleep is disturbed, and often followed by partial night-sweats. The child often talks when asleep, or grinds his teeth; and hence the complaint is often ascribed to intestinal worms, with which, however, it is not infrequently complicated.

94. If the complaint continue, the symptoms are not only increased, but others are superadded. The countenance is more faded and pasty; the upper lip is thick, tumid, or fissured; the throat and fauces red or sore, or the tonsils enlarged; the eyelids and tarsal conjunctives infected, or the pupils are dilated, the conjunctive pale or pearly; the nostrils are somewhat swollen or sore, or discharge a thick mucus; and mucus, mixed occasionally with blood, is passed from the bowels with frequent offensive and gripping motions. These symptoms may continue for some time, the flabbiness and emaciation increasing, and becoming associated with quick respiration, cough, and mucus expectoration, occasionally streaked with a little blood. The skin is harsh and dry, but sweats break out during the night; languor and debility increase; the pulse and respiration are greatly accelerated, and the quickness of the latter relatively to the former increased. The pulmonic symptoms become, in most cases, more manifest, but very much with the age and temperament, or habit of body, of the child. In the very young, the increase of the redness of the bowels, which frequently appears urgent, and is more or less connected with tubercular deposits in the mesenteric glands. In others, the great size of the head and the emaciated state of the limbs lead to the suspicion of incipient disease of the brain or its membranes, which indeed may be actually commencing, either as softening of the central parts of the organs, or as tubercular formations in the membranes; but these changes, as well as those in the mesenteric glands, may be contemporaneous with tubercular deposits in the lungs also, the amount of disease in this organ either predominating or advancing pari passu with that in the others. In many, especially the very young, the pulmonary tubercles never reach the stage of dissolution and tubercular vomic, the disease of the brain, or of the mesenteric glands and bowels, or the extent of tubercular infiltration of the lungs, even of the lower as well as of the upper lobes, terminating life before this stage is approached or advanced, although the emaciation, and the oppression and acceleration of breathing, are extreme.

In these cases the cough and expectoration may be slight; but the fluidness on perpiration, and impaired motion of the ribs, are generally remarkable. The other physical signs are nearly the same as stated above in respect of the early stage of phthisis (§ 54, &c.); but those of percussion are more to be depended on than of auscultation, especially in young children; and, in those particularly, hemoptysis rarely occurs, unless at an early period, and then as merely streaking the expectoration; but slight epistaxis is sometimes observed. The young and the child, the most general are the tubercular deposits in the several organs, especially in the lungs, in the bronchial glands, in the mesenteric glands, membranes of the brain, &c.

96. F. THE DARK RACES are much more exempt from phthisis than the white; but very much depends upon race, and upon continued residence in the same or similar climate, on the one hand, and migration to a colder climate, on the other. Of the degree of prevalence of this malady in different races, some notice, although insufficient, will be taken in the sequel; and I can here only mention the much greater prevalence of this malady in these races, especially the negro race, when they migrate to a temperate, or a cold or changeable climate. As to the usual course of the disease, when it attacks individuals of either a black, brown, or mulatto build, the child not only is not enabled to speak with confidence; but, from what I have seen, it commences silently and insidiously, and advances more and more openly and rapidly to its fatal issue. In some cases the attack appears as a vital blight, by which the lungs are especially affected; a lower range of temperature or greater exposure than heretofore experienced, or other depressing or exhausting causes, whilst they impair organic nervous power, and the assimilating functions, thereby develop tubercular deposits in the lungs, as the parts most predisposed, by structure and exposure, to experience this morbid change, generally without any inflammatory precursors or complications. These races, as far as I have had occasion to observe, rarely or never present the protracted and very chronic states of the malady sometimes seen in the white races; whilst the more marked acute forms are frequently met with, but these generally with fewer indications of febrile or excited vascular action than in the white races. Hemoptysis is, I believe, less frequently observed as a symptom or complication of the disease in the negro than in the latter races, whilst it is a severe and frequent symptom in the mixed races of South America.*

* Dr. Archibald Smith, in a very interesting account of the Diseases of Fever, states that "in Spring, when many severe cases of pneumonia present themselves, the commonest catarh generally appears under a more febrile form, and when it unfortunately affects one of a consumptive tendency, it is frequently the exciting cause of a galloping decay. For at this season it is remarked that consumptive patients, with which the hospitals in Lima are well supplied, lay down very speedily, while at other seasons they linger on for a longer period. Persons who are habitually subject to chronic bronchitis, and troubled with what they call cedro phlegm, or much mucus expectoration, are apt to fall into a fatal decay, as a consequence of an acute attack originating in cold; and others, who have been in a lingering state of health for some time, with a slow fever and a short dry cough, or a cough accompanied with expectoration, especially in the morning, of clear and frosty spuit, are prone to have their fever changed, and to be hurried into a state of catarhal consumption. In cases of the latter kind, it is probable that tubercules may have previously existed in the lungs, except the exception of catarh, only serves to bring phthisis into more decided action. And, indeed, it may be made a question whether those cases of chronic bronchitis, &c.
97. iv. THE STATES OF THE BLOOD IN PULMONARY TUBERCULOSIS. — Before a precise idea can be formed of the states of the blood in this disease, the healthy conditions of the blood should be considered, with reference to sex, age, and temperament, in order that the degree in which the former differ from the latter may be determined. It should not, however, be overlooked, that the chemical analyses of Denis, Lecanu, Becquerel, Rodier, Andrail, Nasse, Gayarret, Simon, &c., have presented slight differences, even at the same age, in the composition of the blood in health, so that the results at which they have arrived may be viewed rather as a close approximation to the truth than as absolute certainty. In addition to the differences arising from sex, age, and temperament, others, hitherto not inquired for, may also exist, especially those depending upon race, climate, and season. After examining the mean results furnished by the above writers, I here give those which I have referred to may sometimes at least, be instances of bronchial irritation, and consequent expectoration, of a mucous secretion, sustained by the presence of tubercles. Whatever be the particular form or primary character of pulmonary consumption, certain states of the atmosphere, depending on different degrees of altitude, appear to be either hostile or favourable to the development of the tubercle, according to the particular locality in which the patient resides. Thus on the coast it is a common disease, terminating in puerperal exhaustion and death, in whatever way it may have originated; but, on the intermedial mountains, and in the temperate valleys of the interior, pulmonary consumption is a rare malady. Failure of strength and health coming on gradually, or as a direct cause of death, with impaired appetite, a slight dry cough, with or without pain at the breast or shoulders, a feeble pulse, with nocturnal heat and restlessness, are symptoms frequently precursory of those which characterise confirmed consumption. This slow fever, so much dreaded by every one as the harbinger of phthisis pulmonalis, and often aggravated by daily provocations, or fretfulness and anger, is always accompanied, if not always preceded, by a diseased condition of the digestive functions. This affection, as I think, well described by Tissot as a disease to which men of letters are subject: — "This slight fever, to which some men of letters are liable, and which, by impairing the nutritive lymph, renders them pale and thin, and throws them at last into a state of decay and consumption, a fever which is directly connected with that which sometimes arises from a strong mental excitement excites the action of the heart and accelerates its pulsations; but more frequently it arises from bad habits, and a faulty condition of the chyle, which irritates the organs of circulation, and so becomes the cause of the fever, and also affects the organs of respiration and delicate and sensible, of a cough, which, united to the fever, may degenerate into hectic fever and phthisis. — Lison, Loc. cit., p. 35." In conformity with these views, which are as applicable to the ordinary cases of incipient phthisis in Lima, as to the explanation of the origin of pulmonary affections in men of letters, according to Tissot, I would remark that the chests of the Limoens, especially the male parts of the white population, are commonly contracted; very rarely open and spacious, except among the dark and labouring classes; and every practitioner accustomed with the medical treatment of these people should constantly bear in mind that their respiratory organs are so delicate and easily affected, that sometimes shivering and washing the face in cold water bring on asthma; and I have already shown how this latter affection may be the precursor of confirmed consumption."— Edinburgh Medical and Surgical Journal, vol. IV, pp. 623.

Dr. A. Smith has here shown the very intimate connection of phthisis with impaired digestion and assimilation, and the want of originality; as well as the limited views of those writers who, since the days of Tissot, have espoused a similar somewhat discordant doctrine. Of houatopy, in connection with phthisis in Peru, Dr. A. Smith remarks: — "Spitting of blood from the lungs is exceedingly common in Lima, and not confined to persons of any particular class or colour, though more prevalent among the labouring inhabitants of European descent; and he points out the frequency of attacks of haemoptysis, not only as a presage, but as an attendant on the early stages of consumption amongst the several races peopling Peru.

98. a. The following table, containing the mean of a number of analyses of the blood of healthy persons, between the ages of 21 and 55 years, shows the differences between the constituents of this fluid in males and females, in 1000 grains, or parts. No. 6. Two analyses by Becquerel and Rodier, as the most precise and as nearly approaching the mean of the other observers.

99. b. The differences of the constituents of the blood at different ages have not been determined with sufficient precision; but according to the researchers of Denis, the water in the blood is somewhat increased after 50 years of age, the solid residue slightly less, the blood-corpuscles are materially diminished, and the albumen nearly the same in quantity. In childhood, the water is increased, the solid residue somewhat less, the blood-corpuscles considerably less than at mature age, and the albumen nearly the same as at that age. Becquerel and Rodier state that, after 40 or 50 years of age, there is a decided and progressive increase of cholestrin in the blood. As puberty approaches and as the generative organs are developed, the blood-corpuscles and iron increase, and the relative proportion of water diminishes; the corpuscles and iron serve to maintain the energy of these organs; and until the powers of these organs begin to flag, the blood experiences little or no diminution of its red corpuscles.

100. c. The constitution has considerable influence on the state of the blood. At equal ages, the solid constituents and haemato-globulin are less abundant in the blood in weak than in strong constitutions. According to Lecanu and others, the blood of persons of lymphatic and phlegmatic temperaments is much poorer in solid constituents, and especially in red globules, than that of persons of sanguineous temperament; the quantity of albumen being the same in all. The following are the results to 1000 parts:—

101. d. The chemical analysis of the blood in threatened and incipient phthisis furnishes the same...
TUBERCULAR CONSUMPTION — COMPLICATIONS

103. c. I may adduce the following as the results of my own observations of the state of the blood in the early and in the advanced stages of Phthisis: —

At an early period, or even before the disease has fully declared itself in the organs of the disease, the fibrin in the blood is much more abundant than in health; the colourless globules are more abundant, and the red globules less numerous; the clot is somewhat smaller, its crisis less, and it sooner loses its cohesion. As the disease advances, and as fibrous tissue is established, the fibrin is somewhat increased, and there is more of the red globules, and the albumen and fatty matter are not very materially changed in quantity. The alkaline salts are slightly deficient, and lime is somewhat in excess. It should not, however, be overlooked, that, among the numerous analyses of the blood in phthisis, there are very great differences in the quantity of fibrin, of albumen, and of fatty matter. I have here given what appears to be the more correct results. Probable of the number of such cases is not so different as the quality, the intimate constitution, and vital relations. In the last stage of the disease, the blood appears still more watery, owing chiefly to the deficiency of red globules; and the colourless globules more numerous than in health. The greatest abundance of colourless globules is probably owing to impaired assimilation, or metamorphosis, of these into red globules. The colourless globules in this, and indeed in earlier stages of the disease, have been mistaken for pus globules, the existence of which in the circulation is doubtful, or at least not satisfactorily demonstrated. The vital crisis, as well as the size of the clot, progressively diminishes. It does not appear that the microscopic appearances of the blood in phthisis are different from those now stated, or that the observations which have been made with the aid of this instrument have furnished any additional facts to those now adduced. (See Art. Scofola and Tuericles, §§ 93, 94.)

104. v. COMPLICATIONS OF TUBERCULAR PHthisis.—It is manifest that tubercles in the lungs, in their several stages and stages of the disease (as shown in the art. Scofola and Tuericles, §§ 101, 102) of originally deficient, or subsequently impaired, organic nervous power, and of the consequent changes in the blood, should not be viewed as a special disease of the lungs, or as limited to these organs only, but as a malady, in which the constitution—the whole frame, is more or less implicated. The earlier changes of organic nervous power and of the circulating fluids being such as now stated, it may be inferred that numerous associated and consecutive alterations will appear at early and advanced stages of the malady, more or less intimately connected with the original mischief, or tubercular vice, either as associated or remote changes, as are more or less remote results. As these severally, and often in various combinations, may be expected to present themselves in the course of phthisis, it becomes important that a brief view should be taken of them, as they are frequently presented to us in actual practice, and nearly in the order of their frequency in which they occur.

105. It will appear from the foregoing, as well as from the circumstances of my not having taken 4 B 3
particular notice of a form of phthisis, recently called dyspeptic phthisis,—a form which Dr. A. Smith has shown above (see note to § 95) to have been the subject of an incorrect diagnosis; as digestion is, as noticed by Dr. Smith, an early attendant upon all the forms of this malady, although in different grades; and even when dyspepsia may be so slight as to be overlooked, especially as regards the functions of the stomach, healthy assimilation and nutrition may be very remarkably impaired. Original or acquired defect of the digestive, assimilating, and nutritive functions is not only the attendant upon the commencement and progress of the several forms of phthisis, but it precedes their origin in more or less manifest grades. Indeed, the malady may rationally be viewed as presenting this procession of morbid phenomena, if we admit the earliest change from health in tuberculous persons, whether hereditary or acquired, to be impaired function of the gastric mucous membrane, defective, organic nervous power—a power which endows and activates the digestive, circulating, and nutritive organs and functions.

106. Hemoptysis.—I have already considered this occurrence as a symptom of phthisis (§§ 49, et seq.). It may also be viewed as a complication of this disease; and it may supervene upon tubercles of the lungs coexisting with either functional and congestive disorder, or with organic lesion, of the heart. Hemoptysis may, however, be caused by congestion of, or impeded circulation through, the cavities of the heart, independently of the existence of tubercles in the lungs; but this occurrence is comparatively rare. The blood may proceed—1st. as a simple exudation from the bronchial mucous membrane, in consequence of the irritation and congestion caused by the tubercular deposits, whether within or without the air-cells and capillary bronchi, and by the impediment they occasion to the circulation in the pulmonary veins;—2dly, from the surface of a cavity owing to the erosion of one or more of the vessels passing to it,—a circumstance of much more frequent occurrence. Lastly, it may be due to blood being expectorated, asphyxia having been suddenly produced by the extravasation (see § 134, and art. Lungs, §§ 165, et seq.);

107. The hemoptysis which takes place at the commencement or at an early stage of phthisis may generally be ascribed to the first of these pathological states; but it may also proceed from the disorders and lesions of the heart already alluded to (§ 51), either independently of, or in connection with, tubercular deposits in the lungs. It should not, however, be overlooked that the hemoptysis may appear in females as a vicarious menstruation: and as such it may be connected with tubercular deposits in the lungs or morbid states of the heart, or with both states of disease, or it may be independent of either of these. When the hemoptysis takes place vicariously of menstruation, the lungs are very rarely free from tubercular formations. But, in whatever mode hemoptysis takes place, the blood, which remains for a time in the bronchi, from or into which it is expelled generally by more or less irritation of the epithelial surface, thereby further complicating the malady. (See art. Hemorrhage from the respiratory organs, §§ 96, et seq.)

108. B. Bronchitis and Inflammation.—Bronchitis, most frequently limited, but either acute, sub-acute, or chronic, is a common complication of phthisis. It may exist in one or other of these states. It is generally confined to the bronchi in a portion of one or both lungs, and more especially to the bronchi in the vicinity of, or communicating with the seats of tubercular deposits or cavitiles. In the first stage of phthisis, these deposits most probably occasion merely a state of irritation, or of sub-inflammation, of the mucous membrane of the adjoining bronchi; but, even in this stage, when external agents, or other causes, aid the operation of this pathological condition, then a more active disease of this membrane is developed, especially if one or more attacks of hemoptysis have occurred, and sub-acute or even acute bronchitis results. The effect of this bronchitis, even at an early stage, is, as we have stated, to develop the crude tubercles and to hasten their softening. When this has taken place, and the softened tubercular matter has made its way into the adjoining bronchi, then a very obvious cause of irritation and of inflammatory action is superadded to these previously existing. Hence, during, and subsequent to, the softening—during the second and third stages, the sputum becomes much more abundant, and its quantity is owing chiefly to the morbid secretion from the inflamed bronchi—unless, indeed, in those very rare cases, when the bronchi is not materially irritated by the disseminated tubercles, or when the softened matter is absorbed and does not pass off by the bronchi. In these stages, the discharge from the surface of the cavities, or the contents of recent tubercular v只有es, are the chief causes of the bronchitis and of its perpetuation; for it is frequently observed, that the morbid appearances, both inflammatory and ulcerative, exist chiefly in, or are limited to, the bronchi communicating with the v只有es or cavities, and that these changes may be traced in, and from, these bronchi to their larger trunks, upwards;—3dly, as well as in the larynx, the same alterations are not infrequently observed (§§ 109, 110); whilst the bronchi which present not this communication, or which extend only to crude tubercles, are either exempt from these changes or present them in a slight degree. Dr. Cawwell, indeed, ulceration even in the minute bronchi communicating with cavities, showing the extension of the morbid action from the latter by means of the discharge from them.

109. C. Inflammation, Ulceration, Edema, &c., of the Larynx, and Trachea are often complications in the course of phthisis. The frequency of this association depends upon the original, concurrent, and consecutive causes, and upon influences and agents acting in the course of the malady. The affection of these parts is to be imputed chiefly to the same changes as occasion the bronchi—to the tubercular and other discharges from the originally diseased parts; and often the morbid appearances may be traced from the bronchi communicating with cavities to the trachea and larynx. In some cases, however, the affection of the larynx, less irritated by the morbid deposition of epithelial matter, commences previously to the softening of the
TUBERCULAR CONSUMPTION—complicated with LARYNGITIS, PLEURITIS, etc. 1111
tubercles, and may be described in these to the
greater susceptibility of these parts, in the early
state of the symptoms, and cause of inflammation and its consequences, and to the
irritation extending to them,—by sympathy and
continuity from the pulmonary and digestive mu-
cous surfaces. In the early, as well as in the
advanced, stages of phthisis, the digestive mu-
cous surfaces furnished many important symptoms
of irritation, giving rise to heart-burn, acute eructations,
&c., which very sensibly affect the larynx and
epiglottis, and kindle disorder, which is not readily,
and even never, put out. That it may thus partly
originate in the digestive organs, is shown by the
circumstance of the lesions being sometimes either
limited to the larynx and laryngeal surface of the
epiglottis, or chiefly found in these parts, the trachea
being comparatively exempt or nearly so.
In other cases, both these and the trachea are
affected more or less; and not infrequently the
inflammation affects all these parts, &c., are limited
to the trachea, and found chiefly either in the
posterior or membranous portion of the trachea, or
particularly the side of it corresponding with the cavi-
tities which exist chiefly or only in one lung. This
limitation of the ulceration to one side of the tra-
chea, very probably is caused by the passage of the
mucous secretion over it during the position of
the patient in bed, which is most frequently on the
back, or towards the side most diseased, so as to
give greater freedom of respiration to the lung
least affected. In some cases, the ulceration of
the posterior part of the trachea is very extensive,
and some of the ulcers very deep, even so much
so as to give rise, in rare instances, to a fistulous
opening into the esophagus, one instance of which
came under my observation. (See art. LARYNX
and TRACHEA.) The larynx is rarely attacked
primarily, or independently of tubercular deposits
in the lungs; it is chiefly in connection with tu-
berculous disease of the lungs and with syphilis
that lesions of this part occur. M. Louis states
that of 180 persons, who died of chronic diseases,
not phthisical or syphilitic, be found one only
with some affection of the organ, while out of
five had ulceration of this part or of the epiglottis,
and one in three had ulceration of the
trachea, among those who died of tubercular con-
sumption.
110. Inflammation or ulceration of the larynx is an
important complication of phthisis; and when the
affectation of these parts is severe, and that of the
lungs not well developed, or at an early stage, the
disease has often been called laryngeal phthisis.
But, in those cases, the affection of the larynx
is merely symptomatic of the tubercular formations
in the lungs, which is often masked by the former
affectation, especially when it is severe or the tu-
berculous deposits not far advanced. In this state
of the larynx there is either hoarseness or loss of
voice, with pain in the region of the os hyoides,
especially when ulcerations have advanced. The
cough is characterized by a harsh grating sound.
It is difficult, suffocative, or attended by a whis-
tling noise. The ulcerations in the trachea are very
frequent in the more chronic states of phthisis, and
are rarely manifested during life in these slow
cases. M. Louis observed in some instances that
secretions of heat and odor of breath were complained
of behind and above the sternum.
111. D. INFLAMMATIONS OF THE LUNGS, limited
to portions of them, and both of these portions and of
their bronchi, especially to parts adjoining the tu-
berculous masses, and causing symptoms at all stages of phthisis. In the first stage, when
the tubercles are crude or disseminated through the
organ, the inflammatory action may, from its
grade, or its congestive or scrofulous character, or
from being masked by the tubercular deposits, be
imperfectly manifested either by the rational symp-
toms or the physical signs. In this stage it is very
difficult to determine whether the tubercles be the
cause of the inflammatory irritation, or the latter
the produce of the tubercles. It is not improbable
that, however originating, the one morbid state
acts, and is acted on by the other. As the tu-
bercles advance to softening inflammatory or con-
gestive appearances may be detected around them,
and the same are often seen around the vomicus in
or near the walls of cavities, the bronchi, both
capillary and large, participating in these changes.
In many instances the structure of the lung is
condensed or infiltrated with tubercular matter around cavities or vomicus, the change being a
result of inflammation of a scrofulous or congestive
character, limited to the situations in which
the tubercular deposits are, or have been, most
abundant or developed. In other instances, es-
specially at an early stage, the attacks of Hemo-
ptyysis, especially when considerable, diminish or
subdue the inflammatory condition, and leave the
portions of lung not yet disorganised in a better
state than previously for the performance of their
functions. In some cases, especially where the
deposits or vomicus are near the surface of a por-
tion of lung, the inflammatory action in the adjoin-
ing structure extends to the pleura, giving origin
to the next complication, namely, intercurrent
pleuritis, which is very frequently associated with
one or more of those already considered.
112. E. INFLAMMATION OF THE PLEURA—in
an acute, sub-acute, or chronic form—most
frequently limited, but sometimes very considerably
extended—generally very sensibly expressed, but
occasionally almost latent or not expressed, or
rather overlooked but that one in five had ulceration of this part or of the
epiglottis, and one in three had ulceration of the
trachea, among those who died of tubercular con-
sumption.

4 B 4
TUBERCULAR CONSUMPTION—complicated with Abdominal Diseases.

nervous influence endowing the vascular system and the circulating fluids. These complications may appear at all stages of phthisis, or they even may appear before. The complication with disease of the digestive mucous surface is one of the most important. The stomach, the lower parts of the ileum, and the caecum and colon, are most frequently affected. M. ANDRAZ justly remarks that "softening of the mucous membrane of the stomach, hypertrophy of the different portions of the intestines, ulceration of the small intestine, accompanied in many instances by a development of tubercules, are all of such frequent occurrence in phthisis, that they may fairly be considered as constituent parts of the disease." These lesions of the digestive canal most frequently occur in the course of the pulmonary disease, often not until an advanced stage, especially in persons somewhat advanced in age; but they sometimes precede it, particularly in children and younger subjects; and, in some cases, the pulmonary and abdominal affection appear to commence at the same time or nearly so.

114. (a.) This is more especially the case as respects the complication with disorder of the stomach. At the commencement of phthisis this complication is usually of a dyspeptic character; but it may, as the disease advances, or even from the first, assume a severer form and be attended by nausea, pain, or vomiting. Tenderness, a sense of heat or burning pain, increased by pressure, are present in these cases, and may arise either from inflammatory softening of the villous surface, or from ulceration. These symptoms and lesions, although early observed in some cases, the vomiting and pain occasionally being severe and obstinate, commonly appear in the second or third stages of phthisis—often in the third. As far as my experience extends, young females have more frequently presented this association than males. Increased size of the stomach was observed by M. Louis in more than two-thirds of the cases examined by him after death, whilst only two instances of it were seen in 230 subjects who died of other diseases. In some cases the organ is double or treble its natural capacity, as low as nearly to reach the pelvis, its coats becoming thinner in the ratio of its increased size.

115. (b.) Disease of the intestines, chiefly of the follicles of the lower portion of the ileum, commencing with tuberculous deposits in the solitary and agminated follicles, and terminating in ulceration of these, is a very common complication of phthisis. The follicles are first distended, enlarged, and projected on the mucous surface by the tubercular deposit; they afterwards burst, discharge their contents, and ulcerate; the ulcers being seated chiefly in the patches of agminated follicles in the lower portion of the ileum, and in the side opposite to the attachment of the mesentery. In the large intestines, especially the caecum, the ulcers are disseminated irregularly. The small ulcers in the ileum generally coalesce, and the larger ones pass under the mucous surface and detach portions of it. They often proceed deeply, as shown in the article on the Digestive Mucous Surface (§§ 36, et seq.), but they rarely perforate the intestines in phthisis, for as soon as they approach the peritoneal surface, lymph is thrown off, and the newly perforated part is absorbed into the opposite peritoneal surface. This lesion of the intestines is generally attended by the obstinate diarhoea which occurs in the second and third stages of phthisis, in the latter especially, and it has usually been chiefly to be ascribed to two morbid conditions, or to either of them, namely to the existence of tubercles in the intestinal follicles, or to disease of these follicles excited by the morbid states of the blood, in the course of the elimination of the morbid elements from this fluid by these follicles.

116. The earlier the ulceration of the intestines takes place in phthisis, the more rapid in general is the progress of the malady, and the loss of flesh and strength of the patient. In the more chronic and protracted cases, this lesion seldom supervenes until shortly before their fatal termination. M. LOUIS states, that he found tuberculous ulceration of the small intestines in five-sixths of the cases he inspected; and almost as frequently in the large intestines; the mucous membrane being about a quarter to one-half thickened and softened in about one-half of these cases. In the whole number of phthisical bodies examined by this physician, the large intestines were in a healthy state throughout their extent in three instances only. In the cases which I have inspected, I have always found the caecum move less or less ulcerated; and in some I had reason to infer that this portion of the canal was the first to be affected; perforation of the caecum and perineal abscess or fistula having taken place in two cases in which I was consulted.

117. (c.) The mesenteric glands are often found tuberculous, especially in young subjects, and in connection with tubercular ulceration of the intestinal follicles. In the phthisis of very young children these glands are rarely exempt. PAPAVENTE says that he found this lesion in one half of the cases of phthisis in children. This proportion is less than I have remarked in this class of subjects. In adults, Louis found these glands tuberculous in one-fourth only.

118. (d.) The liver is found remarkably changed in a very large proportion of phthisical cases. This change consists in the deposition of fat in its structure, this organ being enlarged, fawn-coloured, and of diminished consistence, in proportion to the amount of fatty degeneration. The fatty or oily nature of this change is at once shown by the scalpel on dividing the liver, or by pressing a portion of it on paper, or by subjecting it to heat. The organ is equally changed throughout, and with a rapidity nearly equal to that of the tubercular malady, with which this alteration is intimately connected, and upon which it is dependent. M. Louis states that of 49 cases of this degeneration, 47 occurred in tubercular phthisis; whilst of 230 subjects of other diseases, nine only presented this alteration of the liver, and seven of these had tubercles in the lungs. He further remarks, that it is independent of the patient's age, and of any known cause excepting the existence of tubercles; and that it is not attended by any evident symptom except enlargement, the functions of the organ not being disturbed. Sex appears to influence its occurrence, as of the forty-nine cases seen by Louis, only ten were males. The most remarkable instances of this alteration in connection with phthisis which I have seen, occurred in females addicted to the use of spirits and liquors. In a young female who was thus addicted
from childhood, who had never menstruated, and had died of phthisis about the age of nineteen, the fawn-coloured liver was so remarkably enlarged as to fill the abdomen, the lower edge of it pressing upon the bladder and pelvic viscera, the organ nearly equaling in weight the whole body. In these cases tubercles are rarely found in the liver, unless in children. From my own observation, and from a remark made by Sir J. Clark, this change of the liver is not so frequently seen in phthisical subjects in this country as in France, yet functional disorder of this organ is often observed in the course of phthisis.

119. _G. Various other lesions take place, especially in the advanced course of phthisis, but these are merely contingent occurrences, and seldom, or even rarely, met with. The most important of these are lesions of the heart, in rare cases, occasioning sudden death in the course of phthisis; obstruction of veins from coagula in their canals; hæmorrhoids and fistula in ano; tubercular and granular lesions of the urinary organs, and disease of the sexual organs. These require merely a few passing remarks. — _a. Softening and slight dilatation of the ventricles is sometimes observed in the course of phthisis. In the case of a lady, death took place suddenly in the second stage of the chronic form. The body was examined in my presence, and the only apparent cause of the sudden dissolution was this alteration of the heart. I have, however, seen this change in other cases of phthisis; but, although it may have accelerated the course of the malady, sudden death has not appeared to have been caused by it._

120. _h. Coagula in venous trunks, especially in the extremities, form in rare cases at an advanced stage of phthisis, occasioning great edematous swelling of the limb; and are the results of the morbid state of the blood, and of impeded circulation in the venous trunks rather than of inflammation of these vessels._

121. _c. Hæmorrhoids are occasionally a complication of phthisis, and are produced as much by one of the most frequent causes of the latter, as by irritation of the rectum by frequent action of the bowels, and by interrupted or impeded circulation in the portal vessels, namely, by muscular motion or the state of the bowels. The structures in the vicinity of the anus, and which, with one of its consequences, constipation of the bowels, favours congestion of the hæmorrhoidal veins._

122. _d. Fistula in Ano sometimes occurs in the course of phthisis, more frequently in the early stages. It may be imputed to the same causes as produce hæmorrhoids. It has the effect of prolonging the duration, or to a certain extent arresting for some time, the progress of phthisis. Hæmorrhoids, when they discharge at intervals, have a similar effect to fistula in ano on the progress of the disease, as I have observed in several cases._

123. _e. Alterations, more particularly tuberculosis, of the urinary and sexual organs, seldom supervene, in the course of phthisis, although the function of these organs, especially of the uterine organs, are more or less disordered. Tubercular formations are sometimes formed beneath the mucous surface of the urinary passages in the phthisis of children; and in female adults the catamenia are generally delayed, painful or suppressed in the advanced progress of the malady, which generally assumes a more severe and rapid form when this disorder supervenes. In a case of a young lady, who died about the age of twenty of phthisis, and who had never menstruated, the body was inspected in my presence, and the ovaria were found very small, and their coverings thickened and almost of a fibro-cartilaginous density. The disease had been attributed by me to masturbation, the non-appearance of the catamenia, and the alterations of the ovaria, probably having been caused by this most noxious vice._

124. III. PATHOLOGICAL ANATOMY OF PULMONARY TUBERCLES. On opening the thorax after death from phthisis, the lungs generally do not collapse, or collapse imperfectly. They are more or less increased in weight, in some cases very remarkably. Dr. CLEGENNING found the average weight of the healthy lungs of an adult to be 46½ ounces; and Dr. BOYD, as stated by Mr. ANSELL, ascertained that, in a considerable number of adult males, the average weight of tuberculated lungs was 72½ ounces. The increase is due partly to the tubercular deposit, and partly, in various degrees, by an increased quantity of blood in the vessels, the secretion of tuberculous pus, serous effusion, red or grey hæmatization of the lung, or extravasation of blood._

125. In the early stage of uncomplicated phthisis, when the tubercles are distinct, the pulmonary tissue is crepitant around them; and those which are most superficial somewhat raise the pleura. Distinct tubercles in the lungs, according to HASE, are never larger than hempseeds; when they are described as larger, a congersies must be understood. _Grey and yellow crude miliary tubercles seldom co-exist in the same lung, unless they are deposited at distinct periods._ (See SCOFIELD and TUBERCLES, §§ 65 — 90.)

126. _i. The seats of tubercles in the lungs are somewhat different in adult and young subjects. In adults tubercular deposits are chiefly aggregated in the upper lobes. Miliary tubercles are most abundant in the posterior parts of the lungs, and through the parenchyma at some distance from the pleura, but there are many exceptions to this distribution. In children the whole lung, or large portions of it, are involved in the tubercular deposits, which have appeared to have taken place about the same time._ CARSWELL attributed the earlier and the more abundant formation of tubercles in the apices of the lungs, to the motion of these parts being more limited than those of the lower lobes. The former also are more exposed to the influence of cold externally, and are more accessible to the air, in its varying state of temperature and humidity. Lous, ANDRA, and others consider that tubercles are more frequent in the left than in the right lung. HASE, however, disputes this, but I believe with insufficient reasons. The question as to the tubercular deposit being within the air-cells, or external to them, or in other words in the parenchyma of the organ, is still disputed. MAJERDE, CARSWELL, SCHÖNBERG VAN DER KULY, and others consider the former; whilst ANDRA, ANSELL, and others consider that tubercles may occur in either of these situations, and in any tissue where nutrition or secretion takes place. According to Mr. RAINWY, the earliest indications of tubercles in the lungs are deposits of a transparent or greyish, or yellow-
ish substance in the air-cells, sometimes completely filling and distending them; the minute hemorrhage into the cells surrounding the deposits being still perceptible. The deposits sometimes occur in a few only of the cells, but more frequently they fill all the cells of one lobule; and in this case they press upon these vessels, which soon disappear, the whole lobule becoming solidified, and their condition of tubercular matter. Tuberules in the lungs thus, according to Canwell, originally assume the shape of the air-cells, and are somewhat acuminate in proportion to their projection into the bronchial tubes. When they have been of slow growth, or are deposited in large groups, and occupy numerous cells of a lobule, they resemble the sprout of a cauliflower, the pedicle occasionally extending far into the bronchial tube. In the lungs of nutrimental animals, tubercular matter is often seen filling up the bronchial tubes. As the tubercle increases in size, the central parts become further removed from the surface, which is produced; and consequently these parts have the greatest tendency to lose their vital cohesion, and they consequently are softened; this process generally begins at or near the centre of the tubercle. (See Scrofula and Tuberculi, §§ 73, 74.)

127. ii. The distribution of tubercles in the lungs varies much with the age of the patient and the form of the malady. In adults, in the usual and more chronic forms, the tubercular deposit commences, although in different amounts, generally in the spacers of both lungs, and descends gradually downwards to the lower lobes; the larger and older cavities existing at the apices, smaller ones lower down; and accumulations of softened or crude tubercles, or of both, at the base. This cannot, however, be viewed as an absolute law. The tubercles also in one lung as the left, may be generally further advanced in all their stages than those of the right. Besides one portion of a lung may be the seat of cavities or softened tubercles, all the rest, or the greater portion, of the lung being quite healthy. Tubercular cases are formed rapidly to the patches around tubercles, but extend to the vesicular structure of an entire lobule, and pass on to red or grey hepitisation, or even assume in parts a yellowish colour; the pulmonary structure being quite impermeable to air, firm and friable, the tubercles contained in it being more or less softened. In this state of the disease, the associated or intercurrent inflammation presents the usual scrofulous characters, modified by the peculiar structure and antecedent tubercular deposit.

128. iii. Lesions of the lungs associated with tuberculous.—i. Pneumonia, or inflammation of portions of the lungs, and its usual consecutive changes, are often found associated with the several stages of tubercles. The inflammation may have passed on to red or grey hepitisation; and it may have preceded the tubercular deposits, or may have been consequent upon them, induced by the usual causes of pneumonia; or it may have been produced by the irritation developed and kept up by these deposits. It should not be overlooked, that the changes taking place in the lungs of scrofulous subjects during inflammatory action, may be attributed to the presence of the tubercles themselves. Yet this may not necessarily be the case; and these formations may exist in the lungs even of scrofulous and sanious temperaments without inflammatory action in the lungs being produced by them; this action being chiefly a contingent or intercurrent result of causes unconnected with the tubercular disease.

129. a. According to Louis, Gribolli, Hasse, Ancelle, and others, inflammation primarily attacking the scrofulous subject, may produce an exudation of lymph differing from the usual occurring in pneumonia affecting the healthy person, chiefly in its tuberculous characters, and the disease may run its course, and the exudation may be absorbed; but as frequently, perhaps, the pneumonia of scrofulous subjects is followed by general tuberculous consequences. Rojekesk calls this latter change hepitisation with tuberculous deposit, which, not being absorbed or becoming purulent, ultimately passes into yellow tubercle. According to Hasse this alteration is found more frequently in males, than in females, and in persons from 18 to 35 years of age, than earlier or later in life.

130. The alterations produced by consecutive or intercurrent inflammation of portions of the lungs during the progress of phthisis is manifestly much more frequent than the primary form. Louis states that he observed the results of the first stage of inflammation, commonly occupying a limited space of the lungs in 23 out of 125 cases, and the stage of red hepitisation, generally in the lower lobes in 18 cases. He regards the invasion of pneumonia in these cases as preceding death only a few days, and not peculiar to phthisis, as he observed it as frequently in deaths from other chronic maladies. Although the patient may die of pulmonary tubercles without any inflammatory appearances, yet the tubercles are very liable to irritate and inflame the surrounding tissues, and to render the patient more susceptible of the operation of the usual exciting causes of inflammation.

131. b. This secondary pneumonia generally assumes the lobular or vesicular form, and seldom appears until the tubercles have been developed, or have formed aggregated masses, and engendered irritation in the surrounding structure. The matter exuded by this state of inflammatory action around the individual tubercles or masses, is generally peculiar, scrofulous and gelatinous; the spaces between being healthy. Sometimes, however, the inflammation is not confined to the patches around tubercles, but extends to the vesicular structure of an entire lobule, and pass on to red or grey hepitisation, or even assume in parts a yellowish colour; the pulmonary structure being quite impermeable to air, firm and friable, the tubercles contained in it being more or less softened. In this state of the disease, the associated or intercurrent inflammation presents the usual scrofulous characters, modified by the peculiar structure and antecedent tubercular deposit.
loaded with isolated milnary tubercles, mostly yel-
loowish and soft, but sometimes greyish and more
solid. The yellow and soft tubercles are in the
centres of red or grey superficial ; while
the grey are imbedded in a texture loaded with a
bloody serum. The lungs are tumefied, do not
collapse when the chest is opened, are very dark
coloured throughout, preternaturally soft, and
gorged by dark fluid blood and serum. The tu-
bercles have everywhere the same appearance;
the pulmonary structure around them, for about a
line, is more or less altered, the intervening struc-
ture being still permeable. The bronchial mucous
surface is either dark-red or violet. Recent ad-
hesions between the surfaces of the pleura are not
seen. If adhesions exist, they have been formed
previously to this disease. When the malady has
been slower in its progress, the tubercles are more
united into groups, or are more densely crowded
at the apices and superior lobes, than in the lower
lobes.

133. d. In the more chronic and usual forms of
phthisis, the alterations often associated with the
tubercle gland, are those which are clearly
attributable to chronic inflammatory action, and
consist of desquamation of a red or grey colour, or
of varieties of hue of which these are original
types. The parns thus altered are dense, imper-
movable to air ; the bronchi are filled with a dense
whitish matter, and the natural structure cannot
be traced, the part being firm, but friable, or
readily torn. The cut surface is speckled with
grey inclining to yellow, is diversified with white
stripes and arborescent black patches, and is de-
void of the granulations of acute pneumonia. The
incision is not followed by any exudation, and
pressure yields only a little turbid greyish fluid.
The inferior lobe of one or both lungs is thus
chiefly affected ; the alteration proceeding up-
wards, and meeting the tubercular deposits as they
advance downwards. According to Haase, this
associated inflammatory alteration, which differs
from the effect of common pneumonia in the indus-
tation of the lung, invades only the lower portion
of one lung only, whilst the tubercular deposits
exist in both.

134. B. Extravasation of blood in tubercular
lungs is met with in either a fluid or clotted state : —
1st. It may occur as a simple exudation from the
bronchial mucous surface ; 2nd. It may proceed
from ulceration of the bronchi ; 3rd. Blood may be
infiltated into the parenchyma of the lungs in
connection with congestive pneumonia complicating
tubercles ; 4th. It may be infiltrated not
only into the parenchyma, but also into the air-
cells ; 5th. It may be effused from a laceration
of the structure of the lung ; 6th. It may be
effused from the ulceration of a number of capil-
laries in the partakes of a cavity, or of one large
vessel ; and 7th. It may proceed from the rup-
ture of a cavernous band, or of a vessel or vessels
in such band. In most of these the blood is found
either in a frothy or fluid state in the trachea and
bronchi, or partially esuglated; and coagula are
contained in cavities, and sometimes in the bron-
chial tubes. In these last, the effused blood may
become the seats of tubercles. Extravasation of blood is met with in
all stages of tuberculous phthisis. According to
Haase, it is found chiefly where tubercles have
been rapidly formed in connection with inflamma-
tory action, or when the lungs are replete with
densely clustered tubercles. Carellwai
considers, that the sanguineous effusion is in many
cases owing to the compression of the pulmonary
veins by the tubercular mases, and to the conse-
quent prevention with the return of the whole of the
blood sent to the organ. Both of these explana-
tions may be correct as respects different cases.

135. C. Edematous infiltration of the lung is
sometimes seen, but generally only to a small ex-
tent; and chiefly in the acute form of the disease,
in the more exsudative and phlegmatic habits; or
when phthisis is complicated with disease of the
bronchial glands, or of the kidneys. Bliilley and
Barthel consider that serous congestion or oedema
of the lungs is sometimes connected with the de-
posit of tubercles in children; that it may be pro-
duced by this deposit; but that it most frequently
depends upon compression of the vessels by en-
largement of the bronchial glands.

136. D. Emphysema.—Vesicular emphysema is
frequently found in tubercular lungs, in chronic
cases, in connection with various other lesions,
chiefly in the superior and anterior parts. It
occurs at an early stage, generally in a diffused
form, and is produced by the pressure of disseminated
ligare in tubercular lungs upon the minute bronchi; the
more powerful act of inspiration filling the cells,
whilst the less powerful expiration fails in empty-
ing them. Emphysematous portions of the lungs
rarely contain tubercles. But this alteration is
seldom found to a great extent, and generally in
cases where it had not been detected by the phy-
sical signs: "it is usually seen in the upper parts
of the lungs, and often in conjunction with clea-
tried and collapsed portions. The healing pro-
cess, by absorption of the more liquid parts of
ligare in tubercular lungs, and of tubercular vomicose, by shrivelling
the remainder, by clication of the ulcers, and
obliteration of the blood-vessels and bronchial tubes,"
produces a vacancy in the space within the tho-
rax, and this space is gradually more or less
filled up by the sinking inwards of the walls of the
chest, and by the dilatation of the air-cells in the
adjoining still permeable portions of the lung
this latter result sometimes preventing the occur-
rence of the falling inwards of the partakes of the

137. iv. Softened or liquified tigare.—I have
stated above (§ 126.) the views of Mr. Rainey
as to the softening of tubercles; and those of Laennec,
Lous, Schroder Van Der Kolk, Haase, and
others have been stated in the article Scola and
Tubercles (§§ 76, et seq.). It is not impro-
bable that the process of softening me not be
limited to one only of the modes contended for by
these pathologists, but that when it commences
or proceeds in the centres of the tubercles, it may
also be advancing in their circumstances, owing
to the irritation produced by them, and to the
fluid effused from the irritated tissues surrounding
them; the softening thus advancing from the
centre to the periphery, and from the latter to the
former of the tubercle. Generally it is found,
that softening of tubercular deposits first takes
place, conformably, excepting the progress of the
deposits, in those nearest the summit of the lungs,
and proceeds downwards. With the process of
softening, the pulmonary tissues surrounding the
tubercles become more vascular, and inflamma-
tory or congestive changes take place, extending
more or less in the parenchyma, and ultimately to the pleura, as already shown (§§ 111, 112, et seq.). The results of the softening are, discharge of the liquefied matter into the bronchi communicating with the pleural surface, and the formation of cavities which enlarge by successive tuberculization and softening, by continued discharge, and by the coalition of two or more softened tubercles and small cavities.

139. v. Tubercular Cavities and Vomicae.—A. When softening occurs as mentioned, justly frequently and either:—1st, pulmonary;—2nd, pleuro-pulmonary;—3rd, broncho-pulmonary; or—4th, broncho-pleuro-pulmonary, according to their connections with the principal structures of the lungs. The most frequent seat of vomicae and cavities is the summit of the superior lobes of the lungs. They are sometimes seen only on one side, tubercles on the other side being still crude or softening; but when the disease is of long duration they have formed on both sides. When they are found in the lower lobes, or at the base of the lung, they are usually minute in a tubercle and at the summit. Proceeding from above downwards, the following grades or succession of tubercular alterations are observed:—1st, old cavities, with firm or almost smooth parietes, generally empty:—2nd, more recent cavities with tuberculous deposits in their walls, or softened irregular parietes, containing matters about to be noticed:—3rd, softened tubercules, either isolated or aggregated:—4th, crude tubercules:—5th, semi-transparent grey granulations; and,—6th, healthy creptant lung. This succession arises from the progressive development of the tubercular deposit from the summit to the base. The cavities are generally seated deep in the lung, but in some cases they are superficial or near to the pleura. In the former case they commonly open into the bronchi; in the latter, they are disposed to perforate the pleura, but are prevented by the adhesions formed by this membrane (§ 112). Large excavations are usually seated nearer to the posterior than to the anterior surface of the lungs, where they extend to the interlobar fissure, and even sometimes communicates with other cavities in the lobe below.

B. The form of the cavities varies much. Their size varies from that of a pea to that of a large orange; small cavities are generally spherical or oval; but as they enlarge, their form is more irregular, owing to the softening and disorganization of the parietes having proceeded more rapidly in one direction than in another. Where several large cavities communicate, one unequal and sinusous excavation is formed, sometimes with fustulous tracts, and is very irregular in shape, direction, and size, but terminating in one or more ulcerated bronchi. The number of cavities is often considerable, the largest frequently arising from the union of several small ones. A single excavation is comparatively seldom met with. A cavity is surrounded by crudely tubercular tubercles, with very rare exceptions.

140. C. The contents of excavations may be air; or viscid, purulent, or sanguineous fluids, containing whitish, curdy, tubercular matter, more or less softened; or purulent secretions of a dirty greyish, or yellowish, or yellowish-green colour, sometimes streaked, tinged or mixed with blood; or blood more or less pure, fluid or coagulated. The fluid parietal contents are sometimes facetful, owing to their long retention, a communication with a bronchus not having been formed. Old cavities are often empty; recent ones frequently contain purulent or sanguineous matters, and the softened remains of tubercles. This cavity communicates by a channel from the parietes of the cavity, and the debris of tubercles and of the surrounding tissues, altered more or less by retention in the cavity or by the action of the air. Fragments of the pulmonary structure are seldom found in the excavation, but when seen they are generally attached to, or detached from, the parietes. Bridges or cords are occasionally found stretching across a large cavity: these consist of blood-vessels, whose coats have become inflamed and thickened, their contents coagulated, and, having resisted the disorganising process of the adjoining tissues, had been reduced to cords.

141. Hasse describes the blood-vessels forming bands across cavities as often having their coats reduced to a single, uniform, lardaceous substance; and their canals, which still continue although narrowed, become large and older ideas, with a reddish, fibrinous plug. The bands, or cords, thus formed by the blood-vessels are, in rare cases, either partially destroyed or torn asunder, before their canals are completely closed; and thus the more violent attacks of haemorrhage ensue, and often prove fatal, the cavity and bronchi corresponding being filled full of coagulated blood, and which also often fills, in a frosty state, the trachea. The bronchi are early destroyed; but, even when completely ulcerated, they often do not admit air into the cavity, nor the exit of the matters contained in a cavity; for they are plugged by lymph formed within the parts nearest the cavity, or by tubercular matter or deposits formed within them. The bronchi are not found in these bristles, which are thinner in their middles than at their extremities, the former having been longer exposed to the morbid processes.

142. D. The Parieties of Cavities, when recent, are merely the pulmonary tissues somewhat condensed by exuded lymph, or infiltrated with a greyish matter, or with grey granulations and crude tubercules. They are very rarely smooth, and formed only of the core form of the cavity texture. In rare cases they are coloured by a brownish or blackish melanotic deposit. External to these parieties, which may not extend above a line or two into the pulmonary structure, the parts immediately surrounding them are healthy and creptant. Somewhat older cavities are lined with a slightly adherent and soft false membrane. This lining is friable, white or yellowish, resembles concrete pus, and has no vascular connection with the surrounding tissues. It seems as a deposit on the surface of the cavity from the matters therein contained. In still older cavities, external to this deposit, a membranous, organised layer, of a greyish fibro-cellular substance is formed, and is closely adherent to the pulmonary structure. This constitutes the true cyst or parieties of the cavity. This capsule becomes after a time more organised, and, from fibro-cellular, it is fibro-serous, semi-transparent, and in patches, or more extensively fibro-carilaginous, unless where bronchi pass into the cavity. These latter changes are observed only in very old cavities; and vary in colour, vascularity, density, and appearance, with their duration. The internal surface of these parieties or
TUBERCULAR CONSUMPTION.—PATHOLOGICAL ANATOMY OF.

capsules no longer presents the concrete matter first deposited, and forming the early false membrane, but appears, at a much later period, smooth or velvety, and of a pearl-grey, pishak, or reddish hue.

142. The discharge or the absorption of the contents of vomicae are matters of interest. The discharge takes place by means of the bronchi, which are destroyed in the seats of vomicae, and which become irritated, inflamed, and ulcerated by the matters formed and passed along them; the discharge from the bronchi, communicating with cavities, being often greater than that proceeding from the latter. When the matters contained in vomicae are long retained without having communicated with bronchi, they often become very offensive and irritating to the bronchi and trachea during their discharge, and occasion the inflammatory appearances observed in these parts.

144. F. The absorption of the contents of cavities may be inferred when they are found empty, without any manifest communication with bronchi, — when this cannot be detected upon dissection, and to the base of the lungs. Proof of the discharge of these contents during life. I have already alluded to instances of acute phthisis which terminated fatally without expectoration and cough, but preceded by the typhoid symptoms characterising contamination of the blood by the absorption of morbid matters; and in those the cavities, generally small, were empty, their parietes being soft, or covered by a semi-concrete puriform substance.

145. G. The healing processes presented by tubercles of the lungs have been described by Roget, Boulet, Laurence, Bayle, Bennett, Ancell, and others. Hasse conceives that the excretion of tubercles cannot take place if the amount of tubercular deposit be considerable or great; and if the softening be, as it usually is, attended by the continued formation of tubercles. The degree, or the procession, of morbid change in the lungs admitting of remedy cannot be defined, even if both were objects of precise observation. The states of organic nervous power and of the circulating fluids should be viewed as the chief sources, from which the local lesions are to derive repARATION. And this end can be attained only by supporting this power, by exercise, and by all the nutritive and assimilating processes, and thereby rendering the circulating fluid more vitalised, and less capable of forming or perpetrating the tubercular deposit. Under the influence of this system, and of the improved condition of the blood, morbid products are more sparingly formed; those which are formed have their more fluid parts absorbed; they are consequently atrophied, and their more solid, earthy, or saline parts, as respects tubercles especially, alone remain, either in a passive or inert state, and are increased by subsequent depositions, or exist in such condition as gradually advance their discharge. This is the course usually pursued in the removal of tubercular deposits before cavities are formed, and has thus been termed the process of cratification. (§§ 146, 147.)

146. a. After the formation of these concrescences it may be inferred that the organic elements of tubercle are absorbed, and carbonate and phosphate of lime deposited in their place; so that the concrescences cannot be viewed as the mere solid remnants of the pre-existing tubercules. Hasse remarks that the calcareous deposit, in some cases, especially in young subjects, takes place somewhat rapidly, the outside of the tubercule being then changed into a hard crust, while the central part retains its softness. Occasionally the calcareous matter appears to have been deposited at intervals, producing a series of hard, distinct superimposed strata. Most frequently when the process advances slowly, the tubercules appear like to moist chalk. Thus the volume of the entire mass continues to diminish, so much so that a considerable portion of lung, as may be inferred from the size of the bronchi leading to it, becomes reduced by obliteration and shrivelling, to a hard shell, holding in its centre a chalky tubercle no bigger than a pea. This healing process is by no means rare, its traces being often found in the lungs of very aged persons who have died of different maladies, and not unfrequently also in much younger subjects.

147. b. Tubercular cavities heal in the same manner whether they are connected with several bronchi, or shut out. If exactly the same capsule, resulting from inflammatory dilatation of the surrounding structure, is found, wherein the enclosed tubercular mass is converted first into a chalky pulp, and ultimately into a hard calcareous concretion. The majority of these concretions originate in the small and still closed cavities. They are irregularly shaped, with a granular rough surface, are hard or friable, and often contain mealy or soft nuclei. They are found most frequently at the summits of the upper and of the lower lobes, firmly impacted within a shrivelled and condensed structure.

148. c. Cavities cicatrise in different ways. They may disappear altogether, or contract only to a limited extent. In the former case they are united by a membrane, and filled by a compact the degenerative and assimilative processes, and thereby rendering the circulating fluid more vitalised, and less capable of forming or perpetrating the tubercular deposit. Under the influence of this system, and of the improved condition of the blood, morbid products are more sparingly formed; those which are formed have their more fluid parts absorbed; they are consequently atrophied, and their more solid, earthy, or saline parts, as respects tubercles especially, alone remain, either in a passive or inert state, and are increased by subsequent depositions, or exist in such condition as gradually advance their discharge. This is the course usually pursued in the removal of tubercular deposits before cavities are formed, and has thus been termed the process of cratification. (§§ 146, 147.)

149. When the cavities contract only to a limited extent, and simply lose their original characters, their walls are moulded out of the fibrous layer of shrivelled parenchyma, which now neither contains nor secretes tubercular matter. "These extinct vomicae are frequently seen at the apex of the lungs, and might readily be taken for more
bronchial dilatations, were their real nature not disclosed by the relations of the surrounding pulmonary texture, by the co-existence of crepitaceous masses, and above all, by the character of the membranous lining, which essentially differs from, and does not immediately amalgamate with, the mucous membrane coat of the bronchial tubes." This internal lining usually adheres firmly to the indurated walls of the cavity, and is either thick, reddened, and velvety, or pale, smooth, and thin.

150. The state of the pulmonary structure, both adjacent and more remote, is influenced by the above heating process; and the consequent changes are well described by Hasse. The inflammatory exudation upon which the above alterations depend, often involves the whole of the apex, if not the entire upper lobe of the lung, while the collective bronchial tubes degenerate into white, thread-like ramifications. The involved parenchyma of the lung is now converted into an almost cartilaginous mass, impervious to the air, very scantily supplied with blood-vessels, and presenting, when cut, a smooth glistening surface. Obiterated pulmonary vessels, closed bronchial passages, cavities, and parenchyma infiltrated with plastic materials, are hardly to be distinguished from each other; and the whole adheres firmly, by means of the thickened semi-cartilaginous pleura, to the sunken walls of the chest. A few crepitaceous tubercles are still found scattered throughout the hard, nearly homogeneous mass, which, below, merges sometimes gradually, but more often suddenly, into the healthy texture.

151. d. The deposition of black pigment into the lungs during the healing process is a very remarkable fact. It is found wanting only, or almost wanting, in the rare instances of the repair of tubercular disease by means of calcareous deposits in youthful subjects. In older persons the black pigment is so constant, and so considerable that it might be doubtful whether it be the cause, or the sequel, of the cure of phthisis. "Not alone the parts closely adjoining calcareous tubercles and cicatrizing cavities, but, in like manner, the entire mass of those extensive indurations of the upper lobe, just described, are found densely loaded with this pigment. Even the moist chalk-like residue of tubercular masses is often so imbued, and so exhibits a grayish, blackish tinge." In other cases, where tubercles are more limited, and in young persons, the pulmonary structure is puckered, without induration or extensive obliteratiion; the cicatrices appearing elongated, the crepitaceous residue as isolated granules, and the black pigment uniformly but less densely disseminated in the interstices of the air cells. The cicatrices are surrounded by emphysema and dilated bronchi, and the thorax is seldom found depressed.

152. f. In children the lungs are less the predominant seat of tubercles than other parts, especially the mesenteric and lymphatic glands and the bones. When deposited in the former, the depressions pass through their stages rapidly. In very young children the pulmonary deposits are often latent, death ensuing from the co-existence or superposition of other organs. In those subjects who have died of other maladies, the lungs contain greyish, transparent semi-fluid granules or tubercles, not confined to the apex, but existing equally in the lower lobes. The bronchial glands are at the same time very tuberculous. Billard met with five instances of tubercles of the lungs in new-born children; Hudson and Kennedy in the fetus. I have seen the disease in the lungs of several infants of the age of a few months only. The disease in young children is generally worse, and it usually is of this form up to the age of seven or eight years. In young children the tubercular deposits may be as great or even greater in the bronchial, mesenteric, and cervical glands; in the liver, spleen, brain and its membranes, and kidneys, as in the lungs.

153. I. The tubercular and other lesions, found in the several organs of adults dead of phthisis, are often very numerous. Many of them have been already described when noticing the complications and intercurrent affections of the disease. In the advanced stages, pleural inflammations occur, productive of every variety of false membrane, of adhesions, of miliary tubercles upon the pleura and within the exudations on its surface, and of turbid, reddish, serous or purulent effusion. When the trachea and larynx are affected, as described above (§ 100), as well as in many other cases, the bronchial glands of the neck and those seated along the trachea are similarly affected, and exhibit all the phases of tubercular disease. The heart is quite devoid of fat in most cases. Glied states that he always found the blood within the larger veins and the heart in phthisis to contain pus-globules, to which circumstance, much of the constitutional symptoms may be referred. Louis and Bizzù have remarked that the aorta is always more or less contracted. The alterations of the liver and alimentary canal are always remarkable, and described above (§§ 114—118). From the searches of Louis, More, and Hasse, it would appear that tubercles exist in other organs besides the lungs in the pulmonary phthisis of adults in the following ratio. The bronchial glands were tuberculous in about one-fourth the cases; the mucous membrane of the trachea and larynx in one-twentieth only; the cervical glands in the same proportion; the intestinal canal in one-half the case; the mesenteric glands in more than one third; the mucous membrane of the stomach very rarely; the serous membranes very often, and in the following order of frequency: pleura, peritonitis, and pleuro-pericardium. The liver, spleen, urinary organs, brain, spinal chord, are occasionally implicated. The testicles, and the mucous surface of the Fallopian tubes are also sometimes affected. With the exception of the brain and the heart, the absolute density and weight of most organs, more particularly of the lungs, liver and spleen, are augmented in tuberculous phthisis. It therefore follows, that the enormous loss in weight sustained by the body, amounting, on an average, to about 50 lbs., is due to the loss of adipose substance.

154. IV. TUBERCULOSIS OF THE BRONCHIAL GLANDS. — Bronchial Glandular Phthisis. — The bronchial glands may become tuberculated, either primarily or consequentiy, of similar deposits in the lungs. It is chiefly to the primary form of tuberculated bronchial glands that attention is now to be offered. In those subjects who have died of other maladies, the lungs contain greyish, transparent semi-fluid granules or tubercles, not confined to the apex, but existing equally in the lower lobes. The bronchial glands are at

110. TUBERCULAR CONSUMPTION—PATHOLOGICAL ANATOMY OF.
LINGERING PULMONARY PHAINTHE. PRIMARY TUBERICULOSIS OF THE BRONCHIAL GLANDS GENERALLY COM-
MENCES BETWEEN THE FIRST AND SECOND DECADE, AND FINISHES ITS COURSE WITH THE APPEARANCE
OF PUBERTY; ALTHOUGH ITS CONSEQUENCES ARE SOMETIMES MANIFEST BEYOND THIS PERIOD. IT IS OBVIOUS
THAT THIS DISEASE MAY BE ASSOCIATED WITH TUBERCULOSIS OF THE LUNGS AND OF OTHER ORGANS.
IT MAY, HOWEVER, AND OFTEN DOES, RUN ITS COURSE WITHOUT ANY TUBERCLES BEING DEPOSITED IN
THE LUNGS; OR THE LUNGS MAY BECOME IMPlicated AT ANY PERIOD OF THE GLANDULAR MALADY, AND BE DIS-
ORGANIZED WITH THE GLANDS; OR, LASTLY, BRONCHIAL GLANDULAR PHAINTHE MAY SUBSIDE.

155. The course of bronchial glandular phaithes is generally chronic; and the destruction and
shrivelling of the affected glands proceed so gradually as to allow the organism time to com-
penstate for the loss. "Hence it readily admits of reparation; nor is it in itself perilous, although
accidental circumstances may render it fatal." (Hass, p. 349.) The glands at the bifurcation of
the bronchi are earliest attacked, and first pass through the several morbid stages. Thence the
mass of glandular tissue is divided into three distinct directions:—first, to the sympathetic glands
following the ramifications of the bronchi into the pulmonary structure; secondly, to those placed
between the pericardium and the lungs, and along the esophagus in the posterior mediastinum; and,
thirdly, to those which accompany the large vessels in the anterior mediastinum, and pass from
thence to the trachea and the cervical plexus. Only where tubercles are primarily seated in the
mesenteric glands do they appear to advance to those glands which follow the course of the esop-
phagus, passing thence to the cervical plexus. In some instances they probably originate in the
glands of the neck.

156. An occasion seldom offers of examining tubercles, in these situations, in their nascent states.
In these states they then appear as grey or yellow granules, up to the size of millet-seeds. In a
short time, the glands become so infiltrated with tubercles as to form a yellowish white friable sub-
stance, in which no vestige of the former healthy texture is discernible. They thus enlarge remark-
ably; those at the bifurcation of the trachea often attaining the size of a pigeon's egg, those within
the lung, that of a hazel nut, their size decreasing with their remoteness from the part first affected.
Though but loosely attached in the midst of cell
ular tissue, in the healthy state, they now coalesce
by its medium with the adjoining parts, especially
with the bronchi, acquiring from the hardeness
compressed cellular tissue a firm isolating envelope.

157. These glandular enlargements but seldom produce very marked symptoms of compression of
nerves or blood-vessels, although important trunks and branches run in their vicinity; but it is not
improbable that the slight attention hitherto paid to the lesions of the bronchial glands in children has
led to the misinterpretation of the symptoms and effects produced by them, and to the disorders
actually caused them by being imputed to other
sources. It is extremely probable that spasmodic
attacks referred to (see § 14.), Laryngitis streptio,
and other affections of the trachea and bronchi, are either caused, or aggravated, or per-
petuated, by tubercular enlargements of these

158. The tuberculous deposit in the bronchial glands may long continue without much change;
but more frequently it undergoes softening. Hase
states, that when the softening proceeds from the
centre, one or more small excavations are found
containing a purulent and gritty matter, and the
process is tedious. When the softening com-
mences at the circumference, the filamentous
sheaths of the glands are highly vascular and
puffy, constituting at last a mere cyst around the
thick, yellowish, tuberculo-purulent fluid. From
this period the tumour collapses, its contents
becoming epithelial, or compressed through a passage made by them. Absorption pro-
ceeds very slowly, being carried on chiefly by the
external vascular coat of the tumour, the inside of
which coat has a red velvety appearance. Like
a vomica, it generally possesses an unorganised
membranous lining, formed of thickened pus and
tubercle. The cavity thus produced does not,
however, like the pulmonary excavation, continue
to enlarge: its walls receive no additional depo-
sition of tubercle, but rather protect from this
occurrence; and in no case do two adjacent glands
communicate or form one cavity. On the con-
trary, as the fluid contains are absorbed, the cyst
contracts upon the more consistent residue, which,
lessening gradually, acquires a cætaraceous char-
acter, and ultimately is converted into a hard
concretion. These products are often met with,
even in youthful persons, in the place of one or
other of the bronchial glands, especially at the
bifurcation of the trachea. (Becker.)

159. "When the tuberculous mass has re-
mained fluid until long after puberty, or the dis-
 ease has arisen at a later period, black pigment
becomes deposited, both in the softened portion,
and in the papular matter. It is so intimately
combined with the latter, as ultimately to form an
uniform, black, smearly pulp. In such cases the
tumour, whilst gradually contracting in dimen-
sions, retains the same soft condition for years.
Sometimes separate calcaneous nuclei are found in
the midst of the blackened mass. "This deposi-
tion of pigment within glands, totally degenerate
and partially destroyed, is the more remarkable,
as furnishing a proof of connection with the lim-
paphic vessels. It can scarcely be reckoned an
immediate secretion from the glandular cyst and
necessarily concerned with tubercular constitution,
because this process in other organs (the lungs
excepted,) and especially in lymphatic glands, is
scarcely attended by any deposition of black pig-
ment." (Hase.)

160. Softened tubercle often escapes by per-
forating the bronchial wall, forming generally a
chirurgical saccule, the tuberculo-purulent fluid burst-
ing through the bronchus. Years are in such a case
required for perfect recovery, which is necessary.
about either by the gradual healing of the aperture, whilst the subjacent gland shrivels away; or by the closing of it, ere the contents of the gland are entirely voided; the remainder afterwards passing through the several phases, until it undergoes the calcareous change. Sometimes the irritation is renewed at a subsequent period, and the concretions come away.

161. Various other consecutive lesions supervene contingently upon those now mentioned; but the occurrence individually of so rare occurrence as hardly to deserve enumeration. The chief of these are—1st, the escape of the tuberculated contents of a bronchial gland into the pleural cavity, where the softened glandular mass is situated immediately under the pleura, at the interlobular divisions (Bertron, Rillet and Barthée);—3dly, perforation of the esophagus (Bertron and Labon;);—4thly, simultaneous perforation both of the esophagus of the trachea of the pericardium (Syms;)—and 5thly, perforation of the parietes of one of the large blood-vessels. Of each of these only two or three instances have been recorded.

162. In children, in whom alone this disease appears primarily or independently, the lymphatic glands of other parts, especially of the mesentry, often afford the sole evidence of concurrent disease. The lungs are, in particular, sometimes quite free from tubercles. Papavoine states that of forty-nine children affected with tubercles of the bronchial glands, but thirty-eight had tubercles in the lungs. Killeit and Barthée never found other organs in children tuberculous, without the bronchial glands being pre-eminently so. Still bronchial glandular phthisis in children often induces acute tubercular disease, the lungs, the liver, the spleen, the kidneys, the serous membranes, &c., being all found, in various degrees and frequency, to contain recent tubercles. In adults, on the contrary, in whom either recent, or the remains of former, bronchial glandular phthisis may be discovered, tubercular disease of the lungs always predominates, and is in itself fatal. (Hesse.)

163. VI. DURATION OF TUBERCULAR CONSUMPTION. It is not improbable that tubercles may exist in the lungs of a person, hereditarily or constitutionally predisposed to phthisis, from an early age, in a quiescent state, or without advancing to the stage of softening, without shortening by many years the duration of life. This is more likely to occur when the determining causes of the disease have either been avoided, or have not acted with much intensity. Instances have come under my own observation that have been characterised by the chief symptoms of the first stage, and by occasional attacks of haemoptysis, from an early period of life, and yet they reached to upwards of 60, and in two cases to 68 and 69 years. I have no recollection of an instance of 70 have been passed in such circumstances; but Dr. Gregory mentions a case of a person who was consumptive from 16, and died of the disease, at 72 years of age. Phthisis, with the few exceptions arising from the occurrence of acute states of the disease, is essentially chronic or protracted. In general its duration is much shorter in hospitals, and in crowded workshops and manufactories, &c., in 215 fatal cases at the Hospital for Consumption—in 193 cases observed by Louis, and in 200 noted by Bayle, the duration was as follows:

Although tubercles in an early stage may long remain latent or quiescent, yet when they begin to soften, there is every reason to suppose that their advancement is progressive, although at varying rates, or even so slow as to be nearly stationary. It is manifest that numerous circumstances alter the advancement of phthisis in either way. In the Hospital for Consumption it was observed that of those who died within eighteen months 60.5 per cent. were males, but only 50 per cent. were females; whilst of those who lived beyond eighteen months, 31.5 per cent. were males, but 45.5 per cent. were females. According to the tables of Louis and Bayle, the duration of the disease was twenty-three months, which nearly agrees with M. Andral's experience at La Charité. Sir J. Clark remarks that in the upper ranks of society, where patients have all the advantages of the best regimen, of change of air, and of medical treatment, the average duration of phthisis is probably not much short of three years.

164. VI. THE PROGNOSIS OF PHthisis. The result in most of the cases of consumption will become apparent from what has already been adduced. A. The slower the pulse, and the less acceleration remarked in it by change of posture, cough, and mental excitement, the more favourable may be the opinion formed of the duration, if not of the ultimate issue, of the disease. The absence of the flicker and puriform characters of the spits in the advanced stages, and of the symptoms and signs of pneumonia, pulmonary congestion, pleurisy, &c.; an increase of flesh, strength, and weight, or even the arrest of progressive emaciation; the non-appearance of night or morning sweats or diarrhoea; the respiration remaining only moderately accelerated, or not being accelerated in a much greater ratio than the pulse; the absence of marked anaemia, emaciation and debility, and of the other complications besides those just mentioned; the persistence of accustomed discharges, and the continuance in females of the catamenia in the natural or accustomed state; the tolerably regular discharge of the several secreting and excreting functions, especially those of the bowels; quiet repose during night; a mild form of the hectic fever, and an improvement in one or more of the chief symptoms and signs of the malady, may severally be all viewed as indications...
of a slow or protracted, if not of a curable state of the disease.

165. B. Much less favourable, and indeed most commonly unfavourable, are the following:—Rapidity, softness and smallness of the pulse, or a pulse ranging about or above 110 in the adult; quickness of respiration above the ratio which the respiration bears in frequency to the pulse; the states of the sputum indicating the second or third stages of the disease; the appearance of aphthous on the tongue or mouth; or the symptoms or signs of any of the chief complications described above (§§ 104, et seq.); the occurrence of profuse sweats or diarrhoea, without any obvious cause; inability to lie on either side; great emaciation or the production of bed-sores; manifest anæmia conjoined with great rapidity and smallness of pulse; great dysnæsia and oppression throughout the thorax; suppression of accustomed or natural discharges or evacuations; a clubbed and flattened state of the fingers, and incuration of the nails; loss of the hair, with profuse perspiration from the scalp, neck and chest; pain and constriction extending between the sternum and spine; the occurrence of a wandering delirium during the day or lasting all night; and the loss of appetite for food, are the chief indications of a progressively fatal state of the disease.

166. The hemoptysis so frequently indicating the commencement and progress of phthisis, as well as being an important complication, may, according to its character and amount, be either a favourable or unfavourable occurrence. If it be an early or incipient occurrence, the pulse being neither very frequent nor small; if the pulse fall in frequency, and if oppression in the chest, and difficulty of breathing be diminished by it; if it be of a moderate amount, or even if it be very abundant, and be followed by an amelioration of the symptoms, it may prove even beneficial, by removing pulmonary congestion and incipient inflammatory action, although the presence of a portion of the blood in some of the bronchi may excite them, and cause them to become mucous in surface. When, however, the hemoptysis is very scanty, or merely streaks the expectoration, or if it be brownish, rusty or black, and at the same time scanty or very moderate, it then may be viewed as an unfavourable circumstance, or as indicative of active congestion, or of congestive pneumonia of a portion of lung; if it be abundant, protracted, and the blood very dark and gelatinous, no relief of the oppression and dysnæsia following it; and if, in either case, the pulse becomes even more frequent, and the respiration more rapid, the disease is at its worst. In a case of this last description which I saw a few years ago at Lowestoft with Mr. Worthington, an arrest of the haemorrhage was procured by means of the oil of turpentine, and the recovery became complete under the treatment advised in the sequel. Hemoptysis at an advanced period of the disease, more especially when cavities are formed in the lungs, and the loss of blood large, is always an alarming symptom. The same opinion should be formed if the expectoration be a sanguineous, ichorous, or offensive character, or if it contain shreds or small pieces or patches of disorganised substance or tissue.

167. The existence of these, although clearly indicated by all the usual physical signs, is not a sufficient reason for viewing the disease beyond amelioration or even cure, if the pulse and respiration be not greatly accelerated, and the other symptoms be not unfavourable, and especially if the flesh and strength of the patient be not very much reduced; for one or even more cavities may exist in the lungs; and still sufficient healthy structure may remain to perform the functions of respiration, provided that these functions be not too heavily taxed, and that the remaining lungs be not the seat of inflammatory action or congestion, or of tubercular deposit. The falling in and immobility of the parties of the chest, with great acceleration of the respiration and pulse, difficult respiration, sweats, diarrhoea and aphthous in such cases the indications of a not far remote dissolution. If the patient, not having regressed during winter or spring, experiences an aggravation of all the symptoms upon the sudden occurrence of warm or hot weather, it may be inferred that no amelioration can be expected; for I have observed, that patients thus affected by the transition to a range of temperature of about 70° upwards, generally do not survive above a very few months; and that those who are improperly sent to the climate at an advanced stage, soon have their existence terminated by the injurious change.

168. VII. The Causes of Tubercular Phthisis may be supposed to be fully ascertained, and their influence in producing the prevalent and fatal malady duly estimated, individually and concurrently, by the numerous writers who have treated of its forms and symptoms; yet have these causes been often imperfectly ascertained, or incorrectly imputed, in respect of certain states of the disease, and their sources, nature and co-operation very insufficiently investigated. Hereditary predisposition is fully admitted, but the other remote or predisposing causes, which appertain especially to the parent or parents, and influence the organisation of the offspring, are insufficiently recognised. The predisposition, also, which is generated, and the more direct effects produced in the frame by the disease itself, are especially the topics to be inquired into, whether mental or physical—whether morally or corporeally exhausting—in circumstances peculiar to the individual, by the removal of agents to which the frame has become habituated, or which are necessary to health, and by the action of other agencies, which are either obscure or concealed, or are merely concurrent in their operations with more prominent or commonly admitted causes, are often overlooked or not known; and thus the advantages connected with their prevention and removal are altogether lost. Hence, these causes being unknown or unsuspected, their effects cannot be prevented; and the means necessary to the removal of the former or the cure of the latter, are either altogether neglected, or employed accidentally, empirically, and often inappropriately.

169. When treating of Schoepfla and Tubercles (§§ 13, et seq.), the causes of these generic states of the disease were then fully described; but the causes, which, whether acting singly or in combination, develope this species of malady, require attention, more particularly with reference to their modes of action. Certain of these causes, however, which have been fully considered in the篇167. The article now referred to will hardly be noticed, or noticed only with reference to this specific disease.
whilst others will receive that attention which their importance demands, with due regard not merely of the causation, but also of the prevention of this malady.*

170. The Causes Appertaining to One or Both Parents.—A. The hereditary transmission of phthisis is proved.—1st. By the frequency of the disease in the offspring of parents of a scrofulous diathesis or taint, whether quiescent or manifested by internal or external tuberculosities;—2nd. By the presence of tubercles in the fetus, and in infants of tuberculous, phthisical or scrofulous parents;—3rd. By the existence of tubercular consumption in the offspring of a scrofulous mother or scrofulous father; and the scrofulous parent having died, the children of a parent of a sound constitution, in cases of a second marriage, having been exempted;—4th. By the occurrence of the malady in a family, in which no other cause exists;—5th. By the hereditary transmission of the disease in the lower animals. Delafield states that a phthisical rum produced the disease in from sixteen to twenty sheep.

171. Pithies may be transmitted to the offspring,—1st. As a predisposition, or proclivity, or diathesis, or taint—terms which are nearly synonymous;—2nd. As a latent germ, which may be quiescent for many months or years;—3rd. In a more or less developed state in the foetus. The scrofulous taint of the parent, although quiescent, may give rise to external scrofula, or to internal tuberculosities in the lungs, or in some other organ, or in several organs or tissues, especially in children and young subjects. External scrofula, or external glands which have fully supported, is less likely to be followed by phthisis than the quiescent scrofulous taint; but either condition will transmit phthisis to the offspring. The transmission may not take place in the children, and yet appear in the grandchildren. The predisposi-
TUBERCULAR CONSUMPTION.—CAUSES EXISTING IN PARENTS. 1123

vation, rising either from the scrofulous taint or from declared tubercular disease of some organ or tissue, may remain dormant through life, not having been roused by the exciting and determining causes into activity, or developed in the form either of glandular enlargement, etc., or of tubercular consumption, so that it cannot be inferred, that the offspring of a scrofulous or phthisical parent or parents, who has not been affected with either scrofula or phthisis is, therefore, free from the constitutional taint, or in other words, from the hereditary predisposition. It is manifest, however, and it will appear still more manifest hereafter, that a very varying proportion of those attacked with phthisis in any community or climate shall have been thus affected from hereditary predisposition, numerous other predisposing and exciting causes being sufficient to develop the malady in those not hereditarily or even constitutionally liable to the malady.

172. a. As to the proportion of cases of phthisis that may be referred to hereditary taint, authors differ widely. Revusky says that four-fifths are hereditary; M. Portal, two-thirds; Mr. Ancil, one-third; M. Pierry, one-fourth; Briquet, 36 out of 90; Reuze, 24 out of 35. Mr. Ancil states, that in the Consumption Hospital 12 per cent. of consumptive patients were born of phthisical parents. M. Revusky considers that the children of phthisical parents are doomed to the disease, and such may be the case if they be subjected to one or more of the causes which occur previously to, or during puberty and early manhood. M. LucoL states, that more than half the subjects of tuberculosis have consumptive progenitors. Of 141 persons affected with scrofulous glands, whose family history was investigated by Dr. Balman, the following accounts were furnished:

The Fathers died of phthisis in 9
One or more deaths occurred from phthisis in the families of uncles and aunts on the father's side of 61
Grandfathers on the father's side died of phthisis 11
Grandmothers on this side 17

The Mothers died of phthisis of 11
One or more deaths from phthisis in the families of uncles and aunts on the mother's side of 38
Grandfathers on this side died of phthisis 9
Grandmothers 20

173. In 30 of the 141 scrofulous persons, no death from phthisis in either parents or collateral relations were ascertained; but whether the latter exhibited signs of tuberculous taint or disease does not appear. In the Hospital for Consumption, of 660 males, 122, or 18.2 per cent., and of 341 females, 124, or 36.3 per cent. were predisposed by the disease having existed in a parent or parents.

174. b. As to the relative frequency of the transmission of phthisis in the two sexes opinions are opposed; and statistical information is very imperfect. J. P. Franks, J. Franks, M. Briquet, Richard, and Phillips, favour the more frequent transmission by the father, whilst Naske and others entertain an opposite opinion. From the Report of the Hospital for Consumption it would appear that, omitting those cases in which both parents were consumptive, the father transmitted the disease to sons in 58.4 per cent., and to daughters in 43.5 per cent.; and that the mother transmitted the malady to daughters in 56.5 per cent., and to sons in 40.5 per cent. The numbers from which the above results are calculated are, however, insufficient to be relied upon; nor can the facts be determined with precision, especially as respects the absence of any taint in either parent. In a few cases in which I observed with care the constitution of both parents, the taint existing only in one parent, was communicated in very nearly an equal ratio to both sexes of the offspring.

175. c. The question may be asked, In what manner or way is the hereditary predisposition transmitted? Is it by the general organization or constitutional formation, or by the blood, or by miliary germs? But previously to the consideration of this topic, it may be asked, Is the tubercular taint, either quiescent or manifested by internal or external tubercle, necessarily transmitted from parent to offspring? That it is thus transmitted, when both parents are predisposed or tainted, cannot be doubted. The taint may be latent, not having been developed into active disease owing to the inefficiency of the exciting causes. When, however, one parent only is thus tainted, all, or only some, or even none, of the offspring may be predisposed, the taint being limited to one or more, or extended, in various grades to several or to all. That the constitutional taint may exist in the offspring in the form of miliary germs is possible, inasmuch as several observers as well as myself have detected these germs in the fetus where the taint has been manifested in either or in both parents: but this cannot therefore be considered as the usual manner in which the evil is transmitted. It has been supposed to be always conveyed in the blood— for the taint existing in the blood of the fetus and of the individual into which the fetus is developed in all the stages of growth and existence. This supposition may be correct, but various considerations militate against it. 1st. There is no proof, either chemical or microscopic, of the fact. 2nd. The predisposition or taint being permanent, it cannot be inferred as always existing in the blood, which is continually undergoing changes by the functions of secretion, nutrition, and excretion—by the processes of assimilation and of waste—by the metamorphosis of the globules from the states of those existing in the embryo, through those forming the red blood, to their final extinction by the secreting and excreting organs. 3rd. If it exist in the blood, it must necessarily vary with the changes and constitution of the blood, or even be eliminated from the blood, during the processes just referred to, or by the agents often passing into and affecting the circulation, or in the course of diseases which sensibly alter the states of the blood: but no diminution or alteration of this taint has ever been produced in consequence of any or of all these agencies. That this predisposition or taint is one not existing primarily in the fluids, although more or less manifestly affecting these fluids, both the circulating and the secreted, may therefore be inferred; and that it is...
present in those parts of the solids upon which digestion, assimilation, and nutrition mainly depend, must necessarily appear as a rational conclusion—that it is as much a part of the constitutional conformation of the intimate organisation of the tissues and organs, as of the form and contour of the several parts and features of the individual, and of the states of intellectual and moral development and power.

176. B. The Disorders of the Parents predisposing to Tubercular Consumption in the Offspring are chiefly the scrofulous taint; the syphilitic exanthema; a constitution impaired by mercurial courses, or by excessive doses of mercury; exhaustion of vital power, or the debility caused by age, sickness, excessive sexual indulgences, or by masturbation; and a gouty diathesis. Certain of these have been fully discussed when treating of SCROFULA and TUBERCLES (§§ 25, et seq.); and the dependence of phthisis upon the scrofulous taint fully insisted upon, as regards a very large proportion of the cases, both under that head, and above (§§ 170—175). Others of these sources of the diseases require more than a few remarks at this place. Excessive sexual indulgences, and more especially masturbation, particularly as regards the male parent, have a very marked influence upon the constitution of the offspring, if indeed any offspring be produced by persons thus exhausted. In most instances, the children of these parents are puny, very generally tuberculous, the membranes of the brain, the substance of the lungs and other organs being often the seats of the tubercular deposits to an extent incompatible with the duration of life for any number of years or even of months; or if the effects are not so severely and early manifested, a predisposition is at least communicated to the offspring to external scrofula, in childhood or about the period of puberty, or to pulmonary tubercles about the same epochs or at later ages.

177. a. The Ages and Social Conditions of the Parents are not without influence in favouring a predisposition to phthisis in the offspring. Amongst the most important of these, are premature sexual congress, in respect of either or both parents, and far advanced age, especially of the male parent. The effects upon the offspring are, in all respects, the same as those just enumerated; namely, a very early mortality from internal and external tuberculosis, and a predisposition to tubercular phthisis at early or advanced epochs of existence.

178. b. The influences of circumcision and of uncircumcision, the former as tending to prevent, the latter as favouring, a predisposition to the scrofulous taint, have hitherto been entirely overlooked; or if any attention, even the least, have ever been directed to the matter, it has certainly been by no means adequate to its importance, as respects the constitutional and mental powers of the offspring. The subject has hitherto been viewed entirely as a religious rite, altogether superseded by the doctrines of Christianity; but unjustly superseded by the earliest schismatics in the Christian church—by some of the apostles themselves. Circumcision, however, as practised by the followers of Mohammed is very different from that inculcated by Abraham. By the latter, the whole of the prepuce was directed to be extirpated at a period of life most proper for the operation; whilst the former resorted merely to an incision. The ad-
injuries effects are mainly evinced by the scrofulous diathesis thereby generated in the children, and developed either into external and internal tuberculosis in infancy, or into tuberculous consumption in early or late epochs of existence. It is difficult to say in what sex or parent this vice is most productive of these maladies in the offspring. It is, however, evident that the female who addicts herself to the abuse of intoxicating liquor, and especially during pregnancy and lactation—and there are many both in the middle and lower classes who thus devote themselves and their infants to perdition—will bear an unhealthy fetus, or one which will be imbued with the diathesis and seeds of disease just mentioned; and, if it live so long, will communicate a similar evil to its offspring. How efficiently are our legislators providing the incentives to the destruction of health, constitution, and morals, in the licenses and encouragements furnished throughout the kingdom to the abuse of intoxicating liquors! But what are these important matters, to the higher consideration, to them, of aristocratic interest, family patronage, and the interests of the party? These are matters of early life, and are, in the way just stated, more especially and more injurious to the offspring, and in the way just stated, more especially when conjoined with the other causes of ill-health, which abound in all cold, low, humid and ill-drained localities; in crowded and ill-ventilated houses and apartments, and in crowded or close manufactories and manufacturing towns.

183. c. The use of tobacco in any way, either by smoking, sniffing, or chewing, is most injurious, especially in early life, and as respects its effects upon the constitution of the offspring, more particularly when either of these vices are indulged to excess by the male parent. Numerous instances have come before me of young men who have become habitual tobacco-smokers in early life, and who, having married, have either failed of having a progeny, or of having children that could not be reared; or if they reached any of the early epochs of life, were subjects of tuberculosis in one or other of its forms or seats, and especially of tubercular consumption. (See Art. Poisons, 623, 625, et seq.)

184. §. The Causes of Tubercular Consumption that act chiefly during Infancy, Childhood, and Early Life, or previously to Puberty, have been so fully discussed under Scrofula and Tubercles (§§ 30—64.) that very little is left for me to add at this place. The reader will find the several agencies arranged under this class considered at the place now referred to. There are, however, a few topics thus arranged which require notice, as being of some importance in a prophylactic point of view.—A. Sleeping with very old and debilitated persons is certainly prejudicial to the healthy, both in predisposing to tuberculous consumption, and determining or developing the disease in those predisposed by a scrofulous diathesis or other influences. It may also be associated with other causes, and the results become more immediate and severe.

185. B. Infection.—Emanations from the lungs and skin of persons, in the second or third stages of phthisis especially, are certainly sometimes productive of consumption, in particularly early persons of a scrofulous diathesis, and in those who are predisposed by other causes, or who are subjected to several concurring influences. The inhalation by the healthy of the emanations from the lungs and skin of the consumptive, and the consequent appearance of the disease in the former, may, as in other cases of infection, be productive of its injurious effects only in the circumstances now stated, but the disease is caused by infection nevertheless, although the fact is stated loosely by many writers as one of the propagation of phthisis by contagion, and denied by others, as indeed the infectious nature of nearly every disease has been denied by some, who consider belief in infection to be credulity, and scepticism to be a proof of a "strong minded" physician, or rather of an incredulous old woman. Although phthisis, in the circumstances favourable to infection, may be communicated to others, especially when the healthy sleep in the same bed or apartment with the sick, and although this result is, perhaps, more likely to occur in persons under or about the period of puberty than at a much more advanced age, yet for many years after puberty the person thus exposed and predisposed may be attacked; and this result is the more likely to take place in the cases of married, especially recently married, persons. I state this as the result of my observation; and, although the matter has been discussed from the days of Galen, and the occasional transmission of the disease by infection believed by him, by Ribeius, Morton, Van Swieten, Narducci, Roncali, Chavet, J. Frank, Hufeland, Hildebrand, and many others, and denied by Salmaeus, Castellani, Portal, and numerous other writers, it still remains in dispute.

186. C. Employments, exercises, amusements, and regimen of clothing. Scrofulous employments, irksome occupations, and confinement in close or dark apartments, are more or less influential in predisposing to, or more directly occasioning, tubercular phthisis. The deprivation of out-door exercises and amusements, so requisite at this period of life to the development and strength of the constitution, and the congestion and confinement of numbers in ill-ventilated factories, houses or sleeping-apartments, blight the vital endowments of the frame; and of all the structures and organs, the lungs, like the leaves of a plant—both being the respiratory organs of their respective bodies—are the first to experience, and the most disposed to sustain injury. Nor are dress, night and day clothing, the influence of light, sunshine and temperature, at this period of life, undeserving attention as respects both sexes; for although either of these singly may appear of little importance, yet operating, as they often do, in combination, their effects on the general organisation are often remarkable. The frequent practice of leaving portions of the body uncovered by the dress, without reference to the weather and season, during the early periods of life; the very low temperature of sleeping-apartments during the winter season, in this and some other countries, whilst the confinement of the air by closely drawn
certain that the beds cause the repeated respiration and consequent contamination of the air, thereby inducing feverish, restless and unrefreshing sleep, and a contaminated state of the blood, are in no sense inferior to the medicinal effects of an imperfect development of the body at a period of life when all the aids to health and strength are most especially required. Not infrequently also other agencies are brought into operation with those just mentioned, and these too of no mean importance. But the exercise of light, air, and the salutary influence of the sun's rays on the frame—not infrequently, especially when aided by the causes already noticed produces an elevation similar to that occasioned by this cause in plants; and, although the body grows in height, and the vessels extend in the direction of their axes, as in plants, yet the various structures are loosely, weakly and insufficiently formed, each one being deficient in tone, firmness and vital cohesion. Associated with this state of imperfect organisation, the blood presents a similar defect of assimilation, and an arrested development of the red globules; which, although it may abound in colourless globules, or in those not yet metamorphosed into red globules, these fast are very much diminished in number, or in their usual proportions. Nor should the mental depression, the irksomeness, the weakness of body and mind, occasioned by the circumstances noticed under this category, and their effects upon the youthful constitution, be overlooked. These circumstances, when acting either singly, but progressively, or in various combinations, exert their injurious influence primarily, although not always manifestly, on the lungs. These organs, although generally the first to suffer, are not always the first to indicate disorder. The functions of digestion, assimilation and nutrition often furnish the earliest indications of disease to the casual or superficial observer, but the experienced eye, and the informed mind, detect the antecedents of these, and carry the analysis of the morbid phenomena much farther, and until the agencies producing them are fully disclosed. (See SCROFULA and TUBERCLES, §§ 39, et seq.)

187. iii. CAUSES OPERATING DURING AND SUBSEQUENTLY TO PUBERTY.—A. It is manifest that when the mental states of the upper and middle classes of society, at this period of life, are pursued too far, or to the neglect of those amusements and exercises requisite to health, and to the proper development of the frame, pulmonary consumption will follow in a large proportion of cases, especially when the constitution is predisposed by original conformation, by the strumous diathesis, or by other causes acting in earlier life, or concurrently with this. If these studies are rendered still more injurious by stooping positions, or by pressure of the side against a desk, whereby the actions of the respiratory apparatus are hampered or confined within too narrow limits, the injurious effects will be more certain. But, where these latter causes are not present, others equally injurious may operate; and these may either be too close crotches of the lower regions of the chest, the pressure of unyielding, or insufficiently yielding supports in the stays worn by females; the use of steel supports, which conduct the electricity of the frame from the body into the air, and thereby deprive the nervous system of a salutary stimulus; and insufficient clothing on the neck, upper regions of the chest, and shoulders, or even the complete exposure of these parts without any clothing whatever, are not without their influence in causing the commencing causes, especially where a predisposition to this disease already exists. (See also art. SCROFULA and TUBERCLES, §§ 57. et seq.)

B. Trades, employments, and conditions of life are conducive to pulmonary consumption when they prevent exercise in the open air, or cause them to be followed in cold, low, close, humed, and dark apartments or situations, or in confined, bent, or cramped positions of the body, as by miners, &c. As to the comparative liability of persons pursuing different trades and occupations, no precise information has been furnished, as the number of persons occupied in each of these trades, in connection with the number attacked with phthisis, can rarely be obtained. It is manifest, however, from the researches of Drs. Guy and Lombard, that the deaths from this disease in those who follow low indoor occupations are about double the deaths of those who, and, although it may abound in colourless globules, or in those not yet metamorphosed into red globules, these fast are very much diminished in number, or in their usual proportions. Nor should the mental depression, the irksomeness, the weakness of body and mind, occasioned by the circumstances noticed under this category, and their effects upon the youthful constitution, be overlooked. These circumstances, when acting either singly, but progressively, or in various combinations, exert their injurious influence primarily, although not always manifestly, on the lungs. These organs, although generally the first to suffer, are not always the first to indicate disorder. The functions of digestion, assimilation and nutrition often furnish the earliest indications of disease to the casual or superficial observer, but the experienced eye, and the informed mind, detect the antecedents of these, and carry the analysis of the morbid phenomena much farther, and until the agencies producing them are fully disclosed. (See SCROFULA and TUBERCLES, §§ 39, et seq.)

188. C. The instinctive emotions and desires are more important causes of tuberculous phthisis than is generally supposed by either medical men or others; and this category of causes is most influential in young persons of a scrofulous diathesis, and in those who are otherwise predisposed, more especially by the causes already mentioned.—A. Premature or excessive sexual desires and indulgences, and still more the crime of self-pollution, are the chief of the class of causes in producing tuberculous phthisis, and several other maladies. This crime, for it is no less than a crime, and one most severely, but not unjustly, punished by the Mosaic law when denounced, is one more frequently practised by both sexes than may be believed by those who have not had occasion to inquire into the matter; and it is most prevalent in those who are sanctimonious and Pharisaically censorious of others. The injurious effects of this crime are probably greater in the male than in the female.
especially in causing tubercular phthisis; and it is not improbable that the rite of circumcision among the Jews was instituted partly with the intention of preventing the excitement to the conjunctive of the testes that is liable to occur in the uncircumcised. Various mechanical contrivances for the prevention of the vice in females were employed from very early ages, and several of these adopted in the middle ages may be seen in museums of antiquities. No more certain means of preventing this with nearly six per cent. can be supposed than riding. Instances have come directly to my knowledge of females having relinquished horseback exercise entirely on this account.

190. b. Celibacy may be viewed as a cause of tubercular phthisis, although the reason of its being a cause may not be obvious to many. It is, however, more generally known that the average duration of the life of bachelors is much that of married men. This is mainly owing to the circumstance of their having become addicted to the crime of masturbation. A very large proportion of those who are thus addicted are of very young age, and the advent of these diseases is from this fact, and do not marry; whilst others continue this vice in preference to sexual congress, and often pay the penalty by inducing this or other diseases. Several instances have occurred in my practice of persons having admitted, when afflicted with phthisis, or with any other of the maladies entailed by this vice, that they were conscious of the cause only when too late, and often when their minds and the powers of volition were too much weakened to resist the impulses to its commission. Even married men who had become addicted to it previously to marriage have continued it subsequently, as they have themselves confessed to me in several instances.

191. D. Mental exertion and the moral emotions. — a. Mental exertion, especially when prolonged or intense, is more frequently a concurring than an exciting cause, unless where an original or acquired predisposition to phthisis already exists. It is injurious chiefly about or soon after the period of puberty, when the frame, in all its parts, is not fully developed and consolidated, and when exercise in the open air, and in light and sunshine, which it often prefers, and which is requisite to perfect bodily organization is neglected. This cause is often also heightened by the position of the body, especially by the stooping position, which during mental application is often too long retained.

192. a. The depressing emotions and affections, anxiety, longings after the objects of affection, either absent or lost, disappointments, losses of fortune or friends, &c., severely depress the organic or vital influence, impair digestion and assimilation, and predispose to, if they do not actually occasion, this malady. — c. Under this category may also be placed nostalgia in its various longings for early abodes, scenes and objects, and for the society of early or beloved friends. (See also Arts. DISEASES, the CAUSATION OF, §§ 22, et seq., and SCROFULA and Tuberculosis §§ 61, 62.)

193. iv. CONTINGENT AND ASSOCIATED INFLUENCES OF CIRCUMCISION, OR CONCERNING PHTHISIS. — A. Sex. — According to the Registrar-General’s returns, the deaths during two years and a half (1837, 8, and 9) in England and Wales from phthisis were 146,338, being 69,009 males and 77,329 females; and in 1847 the deaths from this disease were 25,083 males and 28,234 females. Mr. Ancell says, that “from the Irish Reports, it appears that of 133,000 deaths from phthisis, 63,632 were males, and 71,955 females.” In London, however, and in the large manufacturing towns, the proportion of deaths from phthisis in males and females was different. In London, from 1843 to 1846, the deaths were greater in males than in females, by nearly six per cent. According to the returns of 1847, the deaths from scrofula, tuber mesenterica, and hydrocephalus were 8105 in males and 6542 in females; and from phthisis 25,083 males and 28,234 females, thereby showing that, whilst the former scrofulous diseases were more fatal in males than in females, the latter, or phthisis, was more fatal in females by nearly six per cent. (59). In this country, therefore, it appears that females are slightly more liable to consumption than males. In the Metropolitan district, however, the deaths in 1838 from phthisis were 4057 males and 3620 females; and in 1839, 3749 males and 3355 females. The deaths in the district, in 1838, from phthisis were 7687, whilst in the southern counties, the population of which is somewhat greater, they were 5805.

194. B. Age. The several tubercular maladies present a greater or less frequency of occurrence at one epoch of life than at another. Tubercular meningitis and hydrocephalus are most frequent during infancy; mesenteric decline in early childhood; the period of weaning; external scrofula from the period of weaning till puberty; and phthisis from puberty until advanced age. The following abstract from the returns for 1845 and 1846 will show the deaths from phthisis, in London, at successive epochs of life:

195. In 1845 the deaths from phthisis in London at all ages were 3624 males and 3107 females; and from all causes, at all ages, 24,486 males, and 23,536 females; the deaths from phthisis being in both sexes 6731, and from all causes 48,332. In 1846 the deaths at all ages from phthisis were 3729 males and 3161 females; and the deaths from all causes, at all ages, were 24,914 males, and 24,146 females; the deaths from phthisis, in both sexes, being 6800, and from all causes 49,089. From these returns it appears that the proportion of deaths from phthisis among persons advanced in age, the number of cases, AC A.
1129  

TUBERCULAR CONSUMPTION—CAUSES OF.

Thus advanced being continued, contains great
to very mature age.

The following table is an abstract from a
more extended one by Mr. Ancell, which he has
made from the Registrar-General’s returns for 1847,
in which the deaths by phthisis, in all England and
Wales at the several epochs of life, are stated and
compared with the mortality by all causes, and with
the number of persons living of the specified
age in the middle of that year.

197. C. Diathesis and Temperamen predisposes
more or less to phthisis, but it is difficult to de-
termine the extent to which they have this effect.
It is even more probable, and more agreeable
with experience, that original or early-acquired
confomation of the body, arising from causes
affecting the parents, has more influence in pre-
dispersing to phthisis than the temperament, as
they have hitherto been described by physiolo-
gists, or conventionally admitted by medical
writers. Temperaments are so mixed with one
another, with diathesis, habit of body, and with
states of vascular plethora, or its opposite, as to
tenderly to be distinguished with precision, or to be
viewed only as states of constitution, which every
physician estimates conformably with his own
views, although he may not be able to describe
them with precision, or agreeably with the concep-
tions of others. I have nothing to add at
this place to what I have observed above (§§ D, et seq.)
on this subject, and that is much less satisfactory to
myself than I wish.

198. D. Seasons, weather, and atmospheric con-
ditions and vicissitudes, have less direct influence in
producing phthisis than has generally been sup-
possed. They are, however, frequent concurrent and
determining causes, and when they appear
most efficient in occasioning this malady, they
often act by producing catarrh, bronchitis, or
pneumonia, either of which may develop qui-
escent phthisis, into a state of action, or call the
latent predisposition into a more manifest form.
Cold conjoined with humidity, especially when
the already predisposed, or those not accustomed
to these atmospheric conditions, are exposed to
them, and sudden vicissitudes of cold, warmth,
and humidity or dryness, or rapid alterations
of these, are certainly powerful agents, especially
in low situations, in developing phthisis. The rapid
transference of terrestrial electricity into the at-
mosphere, during humid states of the air, has an
injurious influence on persons predisposed to, or
labouring under phthisis. The vicissitudes of
temperature to which many expose themselves
by passing from a very warm apartment into the
cold external air, or from the latter into the for-
mer, and by sleeping in a chamber the tempera-
ture of which is many degrees below that of the
apartments used during the day, are certainly
more or less injurious to persons disposed to
phthisis. In cold sleeping-chambers, although
the body is protected by warm bed-clothes, the
lungs are exposed either to a low range of tempe-
randure, or to a higher range generated by breath-
ing the same air repeatedly in consequence of the
confinement of the air by bed-curtains. No small
injury is often also produced by over-exciting or
over-heating the body, so as to produce copious
perspiration, which often chills the surface, and
throws the momentum of circulation inwardly,
 favouring pulmonary congestion, especially when
the external surface is not protected by flannel
next to the skin. Living in damp or ill-drained
houses, removing into recently-built houses before
the walls are quite dry, and living in those which
are built on a humid or clay soil, without sunk
areas around them, or without sufficient space for
ventilation, are more frequent causes of disease,
and especially of pulmonary consumption, than
they are generally supposed to be, especially in
persons of a scrofulous diathesis, or otherwise
pre-disposed.

199. The influence of seasons on phthisis is
but slight, and almost undetermined. Medical
statistics give very little information on this topic,
and that little is deficient in precision. The re-
turns of the Registrar-General furnish no data
respecting it, for the deaths from phthisis during
the four quarters present little difference as to
number; and when the very remarkable differ-
ces of duration presented by this disease are
considered, it cannot be expected that the deaths
can be an index to the seasons in which the ma-
lady was occasioned.
TUBERCULAR CONSUMPTION — CAUSES OF.

200. E. Climate and Localities. — a. As to the climate of different countries, and as to the influence of situation and locality, either in favouring or in preventing the prevalence of phthisis, our knowledge is still meagre and imperfect. It has been asserted on this subject is more or less inaccurate, the inaccuracy being often in proportion to the dogmatism with which the matter is treated. That some climates and localities present a much greater prevalence of this disease amongst their inhabitants than others is an acknowledged fact; but the degree of prevalence, or the amount of influence attributable to climate only, and the shares which may be imputed to situation, circumstances, habits, customs, &c. of the inhabitants, especially the natives, are either very imperfectly known, or not known at all; even at the best an approximation to the truth only is to be expected. Several writers have stated that pulmonary diseases, and more especially consumption, are rare within the tropics, and among the inhabitants of these countries particularly; but Dr. Wood states that the "records of cases of natives of every part of India show that pulmonary and other similar complaints are at least not uncommon diseases amongst natives of Indin, and only yield in frequency to fever, cholera, and dysentery, presenting every form and variety, and which is to be met with in any other part of the world." Dr. Green states that pulmonary consumption is a prevalent disease in the lower provinces of Bengal; and Dr. Wood, who quotes this statement, remarks that he himself observed the disease extensively amongst the Hindoo race, and the Parsees inhabiting the lower belt of the Himalaya range of mountains." The same writer refers to Dr. Gunther's report of the prevalence of pulmonary disease in Upper India; wherein he states—"tubercular phthisis we have had abundance of, as the detailed autopsies forwarded every month show." (Wood's Pathologia Indica, p. 100. et seq.)

201. b. Dr. Archibald Smith, in some valuable communications he kindly sent me respecting the diseases of Peru, remarks that "In the negro hemoptysis is less frequent, perhaps, as a symptom of phthisis, than it is of disease of the heart or aneurism of the aorta. Hemoptysis is also very often observed in the congestive stage of fever in the Peruvian negro; but with the fever the sanguineous spuita disappear. Comparatively speaking, phthisis is decidedly less common in the negro than in the cross between the negro and Peruvian Indian, or pure Indian bred in the mountains, but migrated to the coast. The mixed races with preponderating Spanish type or blood, constituting the creole white race, nourished in luxury, idleness, and pleasure, and consequently with an unhealthy physical and moral training, are delicate and feeble of organisation; and therefore, of all the different races, the most prone to ailments and falling health, and also most subject to tubercular consumption. In the purely white race phthisis is comparatively rare, except among such youths as are sent from Europe with pulmonary complaints. But, as these are found in mercantile establishments, they are usually sent from one station to another, without trying the benefit of mountain air; for there are few European mercantile establishments. In 1799 Lima contained 52,000 inhabitants, of whom 20,000 were whites, 23,000 of the negro race, 6,000 of the cross of white and Indian, and 3,000 only of the pure Indian. At that period the races were treated in their respective hospitals. The whole deaths by hospital and parochial returns were 2755 for the year given. From the white hospitals 650 deaths that have been reported. The assertion on this subject is more or less inaccurate, the inaccuracy being often in proportion to the dogmatism with which the matter is treated. That some climates and localities present a much greater prevalence of this disease amongst their inhabitants than others is an acknowledged fact; but the degree of prevalence, or the amount of influence attributable to climate only, and the shares which may be imputed to situation, circumstances, habits, customs, &c. of the inhabitants, especially the natives, are either very imperfectly known, or not known at all; even at the best an approximation to the truth only is to be expected. Several writers have stated that pulmonary diseases, and more especially consumption, are rare within the tropics, and among the inhabitants of these countries particularly; but Dr. Wood states that the "records of cases of natives of every part of India show that pulmonary and other similar complaints are at least not uncommon diseases amongst natives of Indin, and only yield in frequency to fever, cholera, and dysentery, presenting every form and variety, and which is to be met with in any other part of the world." Dr. Green states that pulmonary consumption is a prevalent disease in the lower provinces of Bengal; and Dr. Wood, who quotes this statement, remarks that he himself observed the disease extensively amongst the Hindoo race, and the Parsees inhabiting the lower belt of the Himalaya range of mountains." The same writer refers to Dr. Gunther's report of the prevalence of pulmonary disease in Upper India; wherein he states—"tubercular phthisis we have had abundance of, as the detailed autopsies forwarded every month show." (Wood's Pathologia Indica, p. 100. et seq.)

203. c. Upon reference to my notes respecting the diseases of those parts of the west coast of Africa which I visited and resided in for short periods many years ago, and which were inhabited almost entirely by true negro tribes, individuals of the white, Arab, or Moorish races being very few, I find it stated that phthisis, remittent and intermittent fevers appeared very rarely to occur among the former; but when they migrated to somewhat colder climates, even to the West Indies, phthisis was sometimes observed among them; and this became the most fatal malady to them, excepting small-pox, when they were sent to temperate or cold climates. Although dysentery and chronic diarrhoea were amongst the most prevalent and fatal maladies amongst negroes in those parts of Africa, yet the liver appeared less frequently diseased than the spleen in this race; and much less so than in the purely white and mixed races. Amongst negro children, however, I remarked that mesenteric disease was not uncom}

204. F. Race. After considering the distribution of heat over the globe as displayed by the isothermal lines of HUMBOLDT (see Art. CLIMATES), and by the later researches and illustrations of Professor DUFF, I infer that less is owing to temperature than to race and modes of life in the causation of phthisis. There are numerous circumstances which concur with temperature in producing a climate either favourable or unfavourable to the prevalence of phthisis; and of these coldness and humidity of the air, low elevations from the surface of the earth,
sudden and frequent vicissitudes of temperature and weather, are amongst the most influential elements of a climate which favour the production of this malady; whilst a moderately warm and dry atmosphere, considerable elevation above the sea, especially in warm countries, and regularity of season and temperature and weather, greatly diminish the prevalence of the disease, and favour recovery in the early stage of the malady. But these conditions favourable and unfavourable, are so associated with numerous other agencies, especially with the influence of race, of social and domestic conditions, of food, habits, and modes of living, &c., that it is impossible to determine the amount of influence which may be ascribed to each.

205. There can be no doubt, however, that the disposition to phthisis existing in different races or varieties of our species should be viewed in very intimate connection with the climates in which they reside, and with the food and modes of living adopted by them. Having ascertained the frequency of the disease in the aborigines of a country or climate, it is next of importance to know how far that frequency may be modified—diminished or increased—by change to other countries, either colder or warmer, or of higher or lower elevation, &c., and by the adoption of different food and other habits. Our knowledge of these subjects is deficient, and the difficulties in the way of improving it are many; but, before I proceed to draw a few brief inferences closely connected with it, I shall succinctly notice such information as I have found calculated to remove a few of these difficulties. Several of the most important topics connected with this subject, and more especially in connection with pulmonary consumption, are discussed in the Article Climate, to which I must refer the reader.

206. In countries in which the isothermal lines of annual temperature range from 70° to 85°, phthisis appears to be rare among the aborigines; but it is more or less increased in frequency in mixed races, and in those who have migrated from very warm to cooler districts, or from a dry and elevated situation to low and humid localities; but the amount of increase under these circumstances cannot be shown. Upper Egypt and other parts of Tibet, for instance, are places in Western Asia where the annual range of temperature is not much above 75°, or below 65°, phthisis is very frequent, although numerous circumstances combine to occasion external tuberculosis, especially in children, and probably also mesenteric disease; and of these circumstances the most influential are evidently insufficient and unwholesome food, and want of cleanliness. The immunity of these countries, more particularly of Egypt, from phthisis, was well known to the ancients from the days of Aristotle; and hence this country was recommended by them as a place of residence for consumptive patients. It is stated by Charcas, Freyer, Kaye, Kerns, and others, that consumption is seldom observed in Syria and Persia; and MM. Brouard, Boudet and other French writers remark that phthisis is rare in the natives of Algiers and of the Barbary Coast, the mean annual temperature being 68° to 72°. The former of these writers observe, that in Algiers, where periodic fevers prevail, of 40,000 cases in the French army only 62 were consumptive; and that the deaths from this disease were 1 in 102, while in the army in France they were 1 in 5.

In the West India Islands the annual mean temperature varies from 75° to 80°. The statements respecting the firm and dry atmosphere, of these islands vary remarkably, and are often contradictory; but upon the whole it appears that this disease is not infrequent among the dark races, especially negroes who have been brought from Africa, and among creoles. Drs. Musgrave, Davy, and Hunter say that it is rare among the indigenous inhabitants. The reports of Col. Tulloch give five deaths from disease of the lungs annually in 1000 of the population in Jamaica; and a greater mortality from phthisis among white troops stationed in these islands than in their own country, but a much less mortality when stationed in the East Indies.

207. The East Indies furnish a variety of climates, according to latitude, elevation above the level of the sea, and the other elements constituting climate (see Art. Climate). The annual isothermal lines vary accordingly from 66° to 80°; and although it is not important to know how far that frequency may be modified—diminished or increased—by change to other countries, either colder or warmer, or of higher or lower elevation, &c., and by the adoption of different food and other habits. Our knowledge of these subjects is deficient, and the difficulties in the way of improving it are many; but, before I proceed to draw a few brief inferences closely connected with it, I shall succinctly notice such information as I have found calculated to remove a few of these difficulties. Several of the most important topics connected with this subject, and more especially in connection with pulmonary consumption, are discussed in the Article Climate, to which I must refer the reader.

208. As to the frequency of phthisis in Madeira accounts are most contradictory; some writers stating extreme opinions on the subject. Upon the whole it appears, that the disease is not infrequent among the natives, and that it is even common among the lowest class. In Malta, in Italy, Spain, Portugal, Greece, European Turkey, and southern parts of France,—in all the places to which consumptive patients are so often sent from this country,—the disease is more or less prevalent, generally as frequent in all these places as in this country, and in some even more frequent. M. Andreau states phthisis to be very prevalent in the Mediterranean Archipelago. Mr. Spencer Wells says that one-third of the deaths at the Royal Naval Hospital in Malta was from this malady; Dr. B. A. A. on his travels in the Mediterranean, in Italy, France, and England, states that phthisis is very prevalent in the cities of Naples, Nice, Rome, Naples, &c., and not the
TUBERCULAR CONSUMPTION — CAUSES OF.

least remarkable. Mr. Ancell gives the following table of the ratio of deaths from phthisis to all deaths in the civil and military hospitals of these countries:

<table>
<thead>
<tr>
<th>City</th>

</tr>
</tbody>
</table>

In Marseilles the deaths from this disease are stated to be one in four, in Naples one in eight, in Nice one in seven; but these can be viewed as approximations only to the truth. There can be no doubt that, even omitting the deaths from other tubercular diseases, those which occur from tubercular consumption among the inmates of children’s hospitals or institutions, and those brought up in these institutions, are even greater than any just noticed in either of these cities. Dr. Caspar of Berlin gives the following table of deaths from phthisis in different cities in Europe and the United States, the average being one in six:

In Belgium and Holland phthisis is quite prevalent as in England and France. In Sweden the deaths from this disease are said to be about one in nineteen of all deaths. Dr. Gellernstedt remarks that the mortality from this malady in the military hospitals in Stockholm is eight in 1000, and that the life of a soldier is favourable to the production of phthisis, which he believes to be on the increase in Sweden. According to a writer in the British and Foreign Review, this disease is rare in Denmark, and still rarer in Norway, Lapland, Iceland and the Feroe Isles. In Canada, notwithstanding the severity of the winters and sudden alterations of temperature, the air being dry, tubercular maladies, and especially phthisis, are comparatively rare. In Russia this disease is much less frequent than in the southern countries of Europe, although both Sir A. Crichton and Sir G. Leveseure state that external scrofula is very prevalent, especially in St. Petersburg and Moscow, and remark that those who bear about them scars from scrofula are supposed to be exempt from phthisis.

209. In the Southern Temperate Zone, between the isothermal lines of 40° and 70°, comprising the southern part of South America, the Cape of Good Hope, with a portion of South Africa, nearly the southern half of Australia, Van Diemen’s Land, and New Zealand, all accounts lead to the conclusion that tuberculosis is much less frequent than in countries situated to the north of the northern temperate zone. This comparative immunity is owing to the remarkably less liability of the native races to the disease, and to the general dryness of the air, notwithstanding the sudden visciditides of temperature. Other conditions, either not known, or imperfectly appreciated, may also concur to produce this result. In many parts of Australia, however, the quantity of dust so frequently floating in the air, during the hot and dry seasons, in some measure counteracts the other beneficial influences of the climate as respects phthisis.

210. From the statistical information which has been furnished respecting the prevalence of phthisis in different parts of the globe, and which may be consulted in the works referred to hereafter, the influences of race and of the food adopted by races and by the inhabitants of different countries, are not sufficiently considered, or are even altogether overlooked. Although statistics may nevertheless furnish much that is important on this subject, yet there are other circumstances besides these which have not been taken into the account. Of these not the least important are, the influences of religious institutions and rites; of the states of social intercourse; of modes of living and of warming apartments, in cold and in temperate countries; the effects of the soil, of vegetation, of water, and of the emanations from them. Of the agency of these, either in favouring or in counteracting the prevalence or frequency of phthisis, our knowledge is very deficient.

211. From the imperfect information furnished by statistics and by other sources of knowledge, and from what I have stated under Climate, I venture the following inferences as comprising most of what is known of the influence of climate, and of its more important effects, in causing tubercular consumption. — Phthisis is more or less prevalent in the northern temperate zone, especially in the countries of Europe and the United States of North America.

212. b. This prevalence is most remarkable in the Caucasian race, and in the crosses of this race with any other, more especially with the negro and other dark races.

213. c. The natives of countries to the northward of the temperate zone are rarely affected with phthisis while they reside in these countries, and continue the habits and modes of life — of clothing, lodging, sleeping, living, and feeding — which are generally adopted by them; but when they are removed to more temperate climates, and adopt the habits and modes of life of these climates, they evince a manifest tendency to phthisis, which is probably heightened by the nostalgia to which they are subject when removed from their native countries and from accustomed pursuits, habits, &c.

214. d. The negro and dark races inhabiting intertropical countries, and the dark races peopling the islands within the tropics, and those in the southern temperate zone, are rarely subject to tubercular consumption as long as they remain in their native countries and islands, and continue their usual habits and modes of living; but the offspring from a cross with the Caucasian race, especially when they remove to a temperate or cold and humid climate, and still more these native races when they migrate to such a climate, are even more liable to phthisis than the inhabitants of temperate countries.

215. e. The immunity of the natives of the countries to the north of the temperate zone from phthisis is mainly attributable to their active vocations in the open air, to the nature of their food,
and its adaptation to the temperature and climate, to the general dryness of the air, to the warmness of their clothing, whereby the skin preserves its depurating functions, and to the warmth of their sleeping places. (§§ 24, et seq.)

216. f. The immunity, or comparative immunity, of the negro and dark races from phthisis while they reside in their native countries, is chiefly to be attributed to their outdoor modes of living and exercises, to the adaptation of their food to high ranges of temperature, to the influence of miasmatic districts in counteracting the tendency to tubercular consumption, and in no small measure to the increased functions of the skin in these races; these functions being in them more decidedly supplementary of those of the lungs and liver,—more actively depurative of the blood than in the white race. (See Art. Climate, § 22.)

217. g. The greater liability of the dark-skinned races to phthisis when they migrate to a temperate or cold climate, is mainly attributable to the asthenic diathesis of these races, to the depressing influence of cold, especially in cold sleeping apartments; the change in the common habits of the negroes and the natives of the tropics, to the height which a low range of temperature produces upon the organs of respiration; to the change in their habits, modes of living, food, &c. The proclivity of cross-breeds to this malady is partly owing to the causes just stated, in connection with their indolence, their debauched habits, their venereal excesses, and indoor occupations—if occupied at all. The dark races and mulattos, when they migrate to countries whose annual range of temperature is much below that of their native climates, are disposed to congestive or asthenic inflammatory affections of the lungs; in which, owing to the low grades of vital power and vascular action, the morbid exudation is incapable of the usual changes consequent upon ethically increased vascular action; but, instead, assumes the tubercular form, or that state which is incapable of organisation, and equally incapable of absorption, and which undergoes the alterations characteristic of tubercular matter.

218. h. The Mongolian race, especially as typified by the Chinese, does not appear to be more liable to phthisis than the natives of the northern provinces of India and of the countries in Asia between China and Europe. Of the Chinese, as well as of these latter countries, our knowledge is very imperfect as respects the relative prevalence of disease. But from what I can learn, tubercular phthisis is not a prevalent disease among them, at least as long as they remain in their native climates and pursue their usual occupations, habits, and modes of living. How far the various races and tribes inhabiting these vast regions may be liable to this malady when they migrate to either colder or warmer countries, is not known; but the results must manifestly depend upon the many circumstances attendant and consequent upon such migration.

219. i. The food of man increases the disposition to phthisis in as far as it is not adapted to the constitution and wants of the races in their native countries—to the different races inhabiting cold, temperate, and tropical climates; to each of which it is proper to be supplied, as shown in the article Climate (§§ 26, et seq.). This adaptation of food to race and climate extends to the beverages used by the inhabitants of different countries; the neglect of this principle of Hygiene being demonstrated by the destructive effects of ardent spirits in the dark-skinned races, which are so little injurious to the natives of cold countries.

220. k. The influence of clothing upon the frequency of phthisis requires, equally with food, a reference to race; and the considerations which apply to the one appear in great measure to apply to the other. In all races the clothing, and in the dark races the incrustations of the skin, in addition to the slight clothing required by the vicissitudes of season and weather, tend to promote the regular discharge of the cutaneous functions; the fair-skinned races of Europe and America being those in which these functions are least active in health, and most liable to interruption.

221. l. Religion and religious rites may be viewed by many as exerting no influence on the frequency of phthisis or of any other disease in any climate. I believe, however, that religious rites exert some influence, but that the extent of that influence I cannot state; indeed, it would be impossible to ascertain their influence in all countries, and in countries to the eastward and the north of the former. There can be no doubt, however, that the strictness of diet, and the rites of the Jews, notwithstanding several countervailing influences to which they have been exposed during many centuries, have rendered scrofula, phthisis, and gout less frequent among them than among other peoples in their vicinity (§ 178.).

222. m. In our estimates of the influence of climate on the frequency of phthisis in the white races, a cold moist climate, and low situation, and without being miasmatic, or a variable and humid climate, is the most favourable to the production of this disease; whilst a dry, temperate, and moderately elevated situation, with a regular procession of the seasons, or a limited range of temperature, is that which is most likely to diminish the frequency or arrest the progress of the malady. Other considerations connected with climate will be entertained when the prevention of phthisis is discussed.

223. G. Confinement in prisons, barracks, hulks, workhouses, hospitals, and expatriation, &c., are severally productive of phthisis, both in the predisposed, and in those who have evinced no marked predisposition; but in the former most especially. In prisons, hulks, and workhouses several injurious influences, physical and mental, combine to produce a more or less marked effect. Insufficient ventilation and exercise in the open air, want of light or sunshine, deficiency of external warmth, low grades of temperature, conjoined with humidity, low and moist situations, and insufficient or unwholesome food, generally combined with depression of spirits, longings after liberty, and weariness of prolonged or hopeless confinement, are the frequent causes of phthisis among the inmates of these places. Dr. Baly states that, in a period of eighteen years in the Milbank Penitentiary, nearly half the deaths and half the pardons on medical grounds were due to tubercular disease, the frequency of this disease progressively increasing after a few months' confinement; and the rate of mortality in Mohammedan being nearly four times more than that of the metropolis, as regards this malady. Dr. Baly has further shown that a similar increase of phthisis...
among prisoners occurs in other places of confinement, both on the continent of Europe and in the states of North America. Dr. Allen Wenn remarks, on the authority of Dr. Green, that in the jail of Midnapore, in Upper India, in 22° 30′ north latitude, and 87° 25′ east longitude, and at Calcutta particularly, disease of consumption occurs, although in a hot climate, where this disease is but slightly prevalent. In these intertropical prisons the malady often follows attacks of pneumonia, or it assumes the acute and febrile form, or that described as most common in children (§§ 92, et seq.).

224. Many of the conditions existing in prisons are, to some extent, present also in barracks and in workhouses. According to the Army Reports, the British foot-guards are much more liable to consumption than the general London population; and in most stations, both in temperate and in warm climates, the mortality from phthisis in barracks is much greater than among the officers or the general population of the country. As respects the guards, something may be owing to the height of the men, tall men being more frequently predisposed to this disease than those of middle size; but much more is certainly owing to the concentration of numbers in a limited space, to the irregularities and vices of a barracks life, and to the influence of a vitiated atmosphere. The results are similar, and often more remarkable, in large public or private schools, where a large number sleep in one apartment, and breathe repeatedly the same air.

225. Confinement in workhouses and hospitals is injurious chiefly by inducing tuberculous disease, in some form or other, and especially in that of phthisis. In the hospitals for children this is especially the case, as shown by M.M. Rillet and Bartholoz. The continued respiration of the air of an hospital or workhouse, without removal from the wards or apartments into the open air, is even more injurious than breathing a more impure air than that in these places, when exercise in the pure open air is enjoyed during the day; the continued respiration of a vitiated air being more injurious than the respiration after intervals of a much more vitiated atmosphere. The impurity of the air in these places is caused by the numbers breathing the same air in a confined space, by the exhalation from the bodies of the inmates, and by the effluvia proceeding from diseases, morbid discharges, &c. Infants of women confined in lying-in hospitals often become generally tuberculous if they remain long in these places, as I have observed on several occasions when consulting physicians to one of these institutions.

226. Expatriation, either by transportation for crimes, or by emigration, unless the climate to which expatriation takes place be dry and temperate, is generally followed by an increase of mortality caused by tuberculous consumption. Even removal from the high lands and from the scenes of early youth to the low and humid situations in the same latitude, although the temperature be milder, causes an increased disposition to phthisis. This is partly owing to the mental emotions consequent upon the removal so frequent in young persons thus circumstanced, and is greatly increased by the nostalgia produced in these instances (§ 213).

227. E. Poverty, and the vicissitudes of fortune and of life have no mean influence in both predisposing to and exciting tuberculous consumption. MM. Lombard, D'espine, and Lebert have furnished sufficient evidence that this malady is much more prevalent among the poor than among those of the middle and higher classes. Mr. Lombard states that the combined statistics of phthisis in Vienna, Paris, Hamburgh, and Geneva, show that the disease is doubly more prevalent among the poor than in the higher classes. Every competent observer must have remarked the occurrence of phthisis after the loss of fortune, honour, and friends, and have seen mental depression, conjoined with poverty, slowly developing this disease in its most irreparable form, in all temperaments and constitutions, and even independently of hereditary or other states of predisposition. (See also §§ 170, et seq.)
the blood is then poorest and most deficient in red globules. Now, if these states of exhausted organic nervous influence, and of impoverished circulating fluids, be not improved by judicious treatment and regimen, or by change to a healthy air, &c., and more particularly if they are influenced by injurious exposures or agents, digestion, assimilation, and nutrition are liable to be perverted, and tubercular germs are thereby rapidly developed, or are directly or primarily produced.

229. A. Previous disease of the respiratory and circulating organs has no mean influence in predisposing to, or in directly occasioning phthisis. Frequent attacks of catarra, catarrhal fever, influenza, hooping-cough, bronchitis, broncho-pneumonia, pneumonias, &c., are severally calculated to develop phthisis, particularly in the scrofulous and lymphatic diathesis. In these diseases the evil is not always to be ascribed to the development during their course of the germs of tubercle which had previously existed, but to the primary formation of these germs or deposits during their progress and decline, or their wandering periods of decadence, constituting the early stage of convalescence. In this stage excited action has subsided into more or less of exhaustion vital power is locally or generally impaired, the circulating fluid somewhat wasted as respects its most assimilated elements, and the digestive and assimilating functions considerably weakened. Diseases of the heart, especially valvular diseases, causing either congestion of the lungs or hemorrhage from the bronchial tubes, have also no mean influence in developing phthisis; for the congestion thus occasioned is not unfrequently productive of an exudation either into the air cells or into the parenchyma of the lungs, which passes into the tubercular form, or is converted into or becomes the nidus of fully developed tubercles. Similar results may also follow the exudation of blood from the bronchi, especially if the fluid pass into the air cells.

230. B. Exanthematosous diseases are often followed by phthisis; and this latter malady is more likely to originate during the decline of these diseases, or in their early and advanced stages of convalescence, than at an early period. Of all this class of diseases there is none that is more productive of phthisis, or more rapidly develops it, where the germs of the malady already exist, or where a predisposition to it is present, than measles, and this is more especially remarkable in persons about or above the age of puberty. I have often observed persons who, by diathesis, hereditary predisposition, or other circum-stances, were possessed of a consumptive tendency, pass through measles without any marked pulmonary complication, or any pulmonary disorder that could be detected by auscultation or otherwise, and yet, during the progress of advanced convalescence, or even afterwards, indications of inipient phthisis have appeared, especially if any exposure or want of care had favoured the development of the malady. In this, and in others of the exanthemata, the decadence of the disease, and the consequent convalescence present, as just stated, the most favorable occasions for the origination of phthisis, and these should be carefully guarded against.

231. Of all the exanthemata, there is none so unfrequently followed by phthisis as smallpox. It would appear that this latter malady either carried off most of those predisposed to phthisis, when smallpox was a more prevalent disease than it is now, or it conveyed the predisposition to phthisis. I have long remarked, and I believe that others have also remarked, the very rare occurrence of phthisis in any one even but slightly marked with smallpox. It is manifestly otherwise with measles, for what I have stated with respect to its influence on the frequency of Scrofula (§§ 47-49.), is equally applicable to phthisis.

It does not appear that scarlet fever is influential in producing or developing phthisis further than that the debility consequent upon it, during convalescence, requires a careful protection from exposures and other exciting causes of this latter malady. Scarlet fever is often attended or followed by enlargement and suppurition of the glands of the neck, especially in scrofulous subjects; and in these cases, as well as in other scrofulous cases, when these glands suppurate, the liability to tubercular consumption is thereby greatly diminished.

232. C. Suppressed or excessive secretion or excretion is often more or less concerned in occasioning phthisis. The suppression of an accustomed evacuation or discharge, or the drying up of an issue, secon, or ulcer, or the healing of a fistulous ulcer, as fistulae in ano, has been followed by phthisis; but in all such cases as have fallen within my observation the disease had commenced previously, or had even made some progress; the suppression of the discharge, especially of hemorrhoids or the catarrha, or of the cutaneous excretions, having been followed by a more acute form of the disease, or having developed a chronic, or slow and insidious state of phthisis, into the congestive, inflammatory, acute, or hemorrhagic, according to the diathesis or habit of body of the patient.

233. On the other hand, excessive discharges, whether hemorrhagic, secretory, or excretory, may so weaken the constitutional powers—may so depress organic nervous energy and impoverish the blood, by wasting its haemato-globinum, as to be followed by tubercular phthisis, either where a predisposition to it already existed, or where causes tending to heighten the vital condition of the lungs were in operation, as cold, humidity, &c.; excessive losses of blood, by operation or from hemorrhoids, from hemorrhinogia, flooding, &c.; prolonged or improper sucking, diarrhoea or dysentery, enteric fevers, masturbation, and venereal excesses,—have severally not infrequently either caused or developed phthisis, especially where a predisposition to it was present.

234. D. Impaired organic nervous or vital power, or debility, whether hereditary, original, or acquired during childhood, youth or mature age, is more intimately connected with the occurrence of phthisis than is generally supposed, and is directly concerned with the causation of the impaired conditions of digestion, assimilation, and nutrition, which constitute a large portion of that circle of morbid actions characterising the commencement and early stage of tubercular consumption. (See Diseases.)

235. E. Morbid state of the circulating fluids, both the chyle and blood, that are so often present at an early stage of phthisis, or even before this
TUBERCULAR CONSUMPTION — HISTORY OF THE TREATMENT OF.

The state has manifested itself, are the first results of impairment of the organic nervous power; and although comparatively rarely declared in the form of anaemia or chlorosis, yet they consist of a greater or less deficiency of the haemato-globulin, and suppress the red globules, with an excess of the colourless globules, and a weakened crisis or diminished vital cohesion of the fibrin, and consequently of the coagulum.

236. VIII. OF THE OPERATION OF THE CAUSES OF PITIHSIS. — Pitihsis, whether hereditary, congenital and proceeding from causes affecting the parent, or produced by causes acting during early or mature age, generally arises from a concurrence of causes, one or more of which may be much more effective than the rest; they may act either contemporaneously or successively, or the influence produced by one or two may be reinforced or determined by others acting subsequently.

237. i. The causes, then, either affecting the parents, and the offspring through them, or the individual only during early childhood, or successively, in the many modes of combination of one or more that can here, or even here, are of such natures as to impair vital power, especially as manifested by the organic nervous system, and by the organs and functions endowed by this system.

238. ii. As this system actuates the vascular system and the blood, and as it influences also the digestive, assimilating, and nutritive functions, the secretions and the excretions, so it necessarily follows that causes which depress or exhaust, or otherwise impair the influence or power of this system — the organic nervous — will co-ordinate affect the states of the assimilating functions, of the blood, and of nutrition.

239. iii. The following may thus be inferred as the successive or morbid phenomena resulting from the action of the causes of pitihsis, whether occurring singly or in various combinations, or in succession: 1st. Depression of the organic nervous or vital power of the frame, or an imperfect development of this power, owing to hereditary or congenital, or to more immediate or direct causes operating in early or advancing epochs of life; 2nd. Morbid states of the circulating fluids, especially of the chyle and blood, commencing with the slow or imperfect development of the chyle globules, and followed by a slow or impaired metamorphosis of these and the blood globules, or of the former into the latter, — the plasma or liquor sanguinis, with its fibrin, being deficient in vital endowment; 3rd. A wasting or diminution of the red globules, and an imperfect development of the crisis or vital endowment of the plasma by excessive secretion and excretion from the lungs, skin, and bowels; 4th. The nutrition and vital cohesion of the tissues — the organisation of the frame ultimately suffers.

240. iv. These changes in the organic nervous influence or vital power, in the circulating fluids, and in the nutrition of the structures, produced by the causes of pitihsis, may take place contemporaneously and co-ordinately; but they may more reasonably be supposed to advance in succession, however rapidly, impaired organic nervous power accelerating and increasing the other subsequent changes. That this procession of morbid changes actually obtains may be inferred from the modes in which the causes may be presumed to operate; for those causes which primarily and chiefly affect, by depressing or impairing, or imperfectly developing, organic nervous power, as hereditary influence, the depressing emotions of mind, &c., may reasonably be supposed to operate consecutively, and to no slight extent also impede and disorder digestion, assimilation, and the healthy metamorphosis of the chyle and blood globules, and ultimately the nutrition and vital cohesion of the tissues. Many other causes which more directly tend to prevent the development of the chyle and blood globules, or to promote their waste or destruction, as insufficient food, increased discharges, &c., depress organic nervous or vital power, while they impair or arrest nutrition. Certain causes, again, exert a still more extended influence; for they act directly and manifestly, both by depressing or exhausting vital power and resistance, and by accelerating or increasing the waste and destruction of the haemato-globulin; nutrition, and the healthy conditions of both the fluids and the tissues being more or less impaired. The most influential of these last causes are pre-mature or excessive indulgences to both of their natures, are of such natures as to impair vital power, especially as manifested by the organic nervous system, and by the organs and functions endowed by this system.

241. IX. TREATMENT OF TUBERCULAR CONSUMPTION. — HISTORY OF THE TREATMENT RECOMMENDED BY AUTHORS. — It was remarked by Dr. Young, one of the greatest of the many names that adorn the literature and science, not only of our profession, but of our country, in his learned work on “Consumptive Diseases,” that although we may not obtain, from the medical writings of the ancients any great variety of information immediately applicable to practical purposes, we may still feel a sufficient interest in the history of a science which deeply engages our attention, to induce us to inquire, how long the few truths which are fully established with regard to it, have been sufficiently demonstrated. “When, indeed, a fact is once well authenticated, no accumulation of authorities can be sufficient to invalidate its credibility; yet we cannot help placing a greater degree of confidence in opinions which we are, for other reasons, inclined to adopt, when we are informed that they are sanctioned by the observations of the most respectable authors of every age.” It is necessary to premise that, until the commencement of the sixteenth century, the sub-acute and chronic forms of bronchitis, were very generally described and treated as forms of consumption, and even as true tubercular pitihsis; and that this want of precision in the diagnosis of these diseases led not only to a much greater diversity of opinion as to their treatment, but also to a marked difference in the reputed results of the means employed. The general misconception existing among writers respecting the precise nature and seats of bronchitis, and tubercular formations in the lungs, and their consequences, should be kept in recollection in reading the following selections. For it will often become apparent that much of the benefit produced by many of the means recommended was actually not manifested in cases of tuberculous consumption.
but in those of sub-acute, or asthenic, or chronic bronchitis. (See Art. Bronchitis.)

242. Hippocrates frequently mentions tubercular consumption by the name phthisis, phthoe, and phthoe, whereof the age most liable to it is from 18 to 35. He notices many of its most prominent phenomena; as the taste and appearances of the expectoration, the pain between the back and sterno, the frequency of haemoptysis, the quick, wheezing respiration, the cough, the condition of the hair and nails; the sweats, diarrhoea, emaciation, pleural adhesions, &c. His treatment is not always consistent with itself. He advises caustics externally, emetics, purgatives in moderation, oxymel, milk diet, especially asses’, goats’, and mares’ milk, warm from the animal; walking exercise; avoiding the extremes of heat and cold. In addition to these, several other, and often opposite means are advised in different parts of his writings, to which it is unnecessary to refer.

243. In the works of Aristotle we find the earliest notice of the opinion that phthisis is infectious. He had preceded his disease makes the breath corrupt and offensive, and those who approach the diseased person breathe the air vitiated by him.—Plautus mentions resin and honey as being employed by the Romans for haemoptysis; and Dioscorides, the physician of Cleopatra, and the greatest writer on the materia medica in ancient times, recommends sulphur—a substance which has been employed in various forms, even down to the present time.—Areteus considers ulceration of the lungs as genuine consumption, called it phthoe, and gives a good description of the disease. Most of the chapter on the treatment is lost, but in what remains milk diet and sea voyaging are strongly advised.

244. Celsus states that, in genuine consumption, a long sea voyage and change of climate are most advisable, if the strength will permit, and the climate of Alexandria is preferred by him. He remarks that the worst air for any disease is that in which it has originated. Amongst various other means he recommends milk diet, with garlic, leeks, &c., with vinegar; farinaceous articles, occasionally some mild animal food; flour boiled with mutton suet, and some light and aunts of wine. He also advises the cautery on various parts of the chest, and the ulcers not to be healed as long as the cough continues. He mentions several other remedies, as borehood with honey; the juice of plantain; garlic in wine, raw or soft; eggs with sulphur; hisop; turpentine boiled with butter and honey; carriage exercise; sailing on a long sea voyage. For haemoptysis he advises bleeding, cupping, wool wet with vinegar to be placed where pain is felt; a cool apartment, and rest.—The elder Pliny enumerates many substances as specifica for consumption, especially ammonium, a course of milk in the mountains, the juice of plantain; a liniment of bony with honey; goats’ fat in gruel, or with honey and water, and a little rue, and various other means less rational.

245. The works of Galen furnish many prolix and digressive discussions on phthisis. The expectation of cæcumous concretions was first noticed by him. He believes in the infectious nature of the disease. He prescribes vinegar much diluted with water for the hectic; bleeding, an emetic, purgatives, friction, baths, exercise, a mild opiate at night, and removal to Stabiae for the advantages of the air and milk of that place. He remarks that the air of that place is dry, the pastures healthy, the age most liable to it is from 18 to 35. He notices many of its most prominent phenomena; as the taste and appearances of the expectoration, the pain between the back and sterno, the frequency of haemoptysis, the quick, wheezing respiration, the cough, the condition of the hair and nails; the sweats, diarrhoea, emaciation, pleural adhesions, &c. His treatment is not always consistent with itself. He advises caustics externally, emetics, purgatives in moderation, oxymel, milk diet, especially asses’, goats’, and mares’ milk, warm from the animal; walking exercise; avoiding the extremes of heat and cold. In addition to these, several other, and often opposite means are advised in different parts of his writings, to which it is unnecessary to refer.

246. Celsus Aurelianus gives a tolerably correct account of the disease by the name of phthisis or phthoe. The medicines he prescribes are honied water, fennel, greek, iris, aristolochia, asarum, and borehood; also fructes, with honey and liquorice; and discodium with butter and honey. Sailing especially to a distant climate and residing abroad are also advised. He censures the use of emetics, and considers the cold bath dangerous.

For haemoptysis he directs astringent electuaries, and pomegranate with aloe, as advised by Terebinthus. If the phthisis continue in moderation, he prescribes bloodletting on the third day, as inflammation will then take place; but if the symptoms are urgent with dyspnoea, bleeding should be practised at an earlier period.—Oribasius gives mere bloodletting as practice, and remarks that a milk diet is of more importance than all other remedies.—Areteus makes a similar remark respecting asses’ milk. He also recommends mutton fat dissolved in soup, and caustics to the chest.—Alexander Trallian gives ripe fruit for the hectic of phthisis, especially grapes. When convulsions are expectorated he employs a cooling diet; and for the cough the juice of lettuce with liquorice; and the discodium for relieving thirst and excessive perspiration. He also mentions the hermodactyla and their combinations. In the writings of Paulus EGONETAS and Acturrius, there is nothing beyond what is contained in the works of Galen.

247. The Arabian writers exhibit no views of the nature and treatment of phthisis different from those which have been given by the Greeks. Ruizes, the most original of these, strongly recommends a mace was first noticed by him. He believes in the infectious nature of the disease. He prescribes vinegar much diluted with water for the hectic; bleeding, an emetic.
phor lozenges; in the early stages bleeding; and generally a dry air, a milk diet, and sugar of roses. In all else he closely follows Galen.

248. The medical writers of the fifteenth, and of the first half of the sixteenth century, follow the doctrine and practice of the ancients, with the exception of Paracelsus. He recommends a powder for phthisis, containing crude antimony and crocus maris. He considers diet to be of the greatest consequence; and advises a bath to be tried containing a decoction of herbs with sulphur.

— Fserrat was the first to notice digitalis, but in a very imperfect way. Fernhuy, whose reputation was high in the sixteenth century, praises asses' milk, and small bleedings for hemoptysis; in all things he principally followed Hippocrates. Lommel notices the infectious influence of the expectation and breath in phthisis, and the hereditary character of the malady. The work of Nicolas Piso is only a compilation from Galen and other ancient writers. Prosper Alpinus merely states, in his work on the Diseases of Egypt, that phthisis is one of the endemic maladies of the country. Serpieri was amongst the first to give careful notice to cases in detail; but he professes merely to follow the doctrines and practice of Galen. Among the means which appear to have been most beneficially used by him in consumptions are asses' and goats' milk; and sulphur with the white of egg. Schenk notices the use of turtle in phthisis on sugar and flour for hectic; but his materials are chiefly compiled from other writers. Most of the remedies he mentions have been already noticed; but we find that Avenzoar prescribed olive oil, Rosmar sulphuric acid, and J. G. Schene the balsam of sulphur, in phthisis. The voluminous writings of Ballonius or Bailleul, a physician in large practice in Paris at the end of the fifteenth century, contain nothing more deserving notice respecting phthisis than a remark as to the expectoration, and bleeding in the nose in those who have nursed others affected with it.

249. Poterius, a physician to the French court, struck out novel modes of practice in this disease, but kept the preparation of most of his chemical medicines secret. These, as far as they are known, seem to have been mixtures of tin, of mercury, of silver, of antimony, of gold, &c., with various other substances. He employed sugar of lead as a refrigerant; and a preparation which, under the name of the antiehect of Poterius, long enjoyed a great reputation. Dr. Young states that this medicine appears to have consisted of two parts of tin and one of antimony, oxidized by means of nitre. He professes to have cured phthisis by giving five drachms of balsam of sulphur every morning with syrup, and the antiehect in the evening, sulphur lozenges and iris being held constantly in the mouth, with a diet of wine and animal food. The balsam of sulphur he recommends to be made with the oil of almonds, and given in milk; other oils make it too heating. Spicelius states that consumptions are more common in England than elsewhere, owing to the habit of confining the lothiest of females by tight dress; and that in Venice, where this habit does not exist, females are more healthy.

250. Sennerius, whose works were very generally confided in at the commencement of the seventeenth century, closely follows Galen. He considers the deliber, discharge, &c., to depend, in phthisis, upon an acid or morbid secretion generated in the lungs. He prescribes many medicines, especially rhubarb, with infusion of roses and goats' whey; and he cautions against too copious evacuations of any kind. He advises an issue in one or both arms, if the delirium and emaciation be not extreme. He remarks that sulphur was first recommended in phthisis by Dioscorides; and he makes favourable mention of honey, roses, borehound, hyssop, &c. He quotes other authors in favour of quassia and ginseng. Boverius, in his Medicine of the Indies, gives a case in which he supposes that fragments of the bronchi were expectorated, but which are mere false membrane formed on the bronchial surface. For true consumption he praises his opiate extract of saffron, which he says stops bleeding, quiets the cough, and has alone cured many desperate cases. He also prescribes conserve of roses with poppy seeds and sulphur, and decoction of ginseng or of sarsaparilla. Verily there are much worse modes of treatment employed in recent times than those adopted by Sennerius and Boverius. Tulpen furnishes nothing that deserves notice than the advantage obtained in a case of the disease by eating oysters daily. — Fabries Hildanus describes several dissections of phthisical subjects, and notes the complication of pulmonary with mesenteric lesions, and the presence of calcareous concretions in the sinali fœminœ. He relates several instances of successful recourse to setons.

251. Our countryman Bennett, as Van Swieten and Dr. Young very justly remark, has much surpassed his predecessors, and most of his successors also, as a writer on consumption, which he experienced in his own person. He pays marked attention to the breathing and the spits, to the prognosis, and to the several contingent affections in the course of the disease. For hemoptysis, leading to phthisis, he advises bleeding, warmth to the extremities, and a medicine from the feet in females, if the catarrh be scanty or suppressed. He recommends milk and milk diet, but prefers medicated whey, and reprobates the use of saccharine substances, as productive of an injurious fermentation. He considers the best expectorants to be those which are hot, and helps to the respiration. Bennett also has recourse to frictions and fomentations, and to balsamic fumigations. These last should consist, in his opinion, of frankincense, turpentine, and styrum, with cinnamon, clofs, and other articles, made into a powder or troche, and burnt on coals. He prescribes also mixtures of herbs, on which boiling water is poured, and the vapour to be inhaled by holding the head over the vessel containing them. Issues are much praised, and, according to my experience, with very great justice. He directs them in various situations, according to the symptoms, and he considers that they may be kept sweet by using pees of orris root, and when the discharge should be promoted equal parts of hermodactyl and wax. He recommends Welsh flannel to be worn next to the skin, and not to be too frequently changed. Animal food, neither very fat nor lean, is allowed, and a gentle emetic is given when the stomach is loaded, and a decoction of sarsaparilla and other woods with ginseng is recommended for drink. If we except the recent employment of eel liver oil in phthisis, in what, it may be asked, has the treatment of this disease been advanced
since the appearance of the work of Bennett, by the voluminous writings of specialists and stethoscopists in recent times?

252. The continental writers of the middle of the 17th century afford very little information as to the treatment of phthisis beyond what was previously known. Silvaticus considered chiefly in bleeding, issues, and sulphurated lozenges. Reventius notices the infection of persons who had nursed phthisical patients. Among the many substances already mentioned he particularises guiacum, Peruvian balsam, and the stomachic, and the diaphoretic gold, of Poterius. Baltholin furnishes nothing deserving notice further than that sitting apartments may be made, by suitable vapours or medicated efluvia, useful substitutes for a voyage to Egypt or other warm countries. Sylvius attributed phthisis to the existence of glandular tubercles, which, when in a state of suppuration, constitute the nomen. For the cure of the disease he administers opiates, demulcents, and emulsions, fumigations, decoctions of the woods, hermodactylis, &c. He praises balsam of sulphur, and he warmly upbraid practice in the use of it. He says that it facilitates expectoration and relieves the breathing. He considers the milk of sulphur to be much inferior to it. To promote the appetite he prescribes the elixir proprietatis, which is made of myrrh, saffron, aloes, sulphurous acid, and spirits of wine, digested together. The diet he allows comprises wheaten bread, broths, milk, yolks of eggs, biscuits, with a little generous wine.

253. Gibbons Harvey gives a tolerably good description of phthisis, notices bleeding, and remarks that great caution is required in practising it. He prefers whey to milk, gives it liberally with conserve of roses, and mentions the imperatoria as being recommended to him for this disease. Wills remarks that the atmosphere of towns is not always unfavourable to consumptive patients, for he has observed many have better health and less cough in London than in the country. He prescribes sulphur in all forms, several balsams, and tar-water. After bleeding he advises narcotics, the musculus pyridatus, warm bathing, frictions, blisters, &c. Disenbrock mentions the case of a person who was cured by taking goats' milk thrice daily for three months, without any other medicine. Benetus furnishes some information as to the lesions formed in phthisical cases, but it is of a very loose and imperfect kind, chiefly furnished by former writers, many of them of little reputation.

254. Of the writings of Svedenbam, which have been extravagantly praised, but which are now more justly estimated, Dr. Young justly observes, that "among the practical writers on consumption he cannot be considered, even by his warmest admirers, as holding a distinguished rank." His pathology of the disease hardly deserves notice. For a confirmed consumption, medicines are, he remarks, of little use; but bleeding, mild purgatives and pectoral remedies may be beneficial, with or without a relapse. For four days he gives refrigerents, ases' milk, emulsions and opiates. For hemoptysis he directs bleeding, cathartics and the avoidance of animal food. Horse-exercise is very strongly recommended by him; and he states, with the truth that many cannot fail to appreciate, that riding eures consumption as certainly as bark cures intermittents. Carriage-exercise is also praised by him. For simple cough he prescribes astringence from wine and meat, for a few days; ten drops of aniseed balsam of sulphur, taken occasionally on a lump of sugar; lozenges containing liquorice, alecanum, anise seed, anglicana, iris and sulphur; and a liniment of oil of almonds, with syrup of capillaire and violets. If the cough be obstinate or attended by fever he orders bleeding and cathartics; and, if the patient becomes consumptive, ten drops of Peruvian balsam, three times a day, a decoction of bitter plants, riding being the chief remedy. G. Harvey, after ridiculing the treatment of consumption proposed by his predecessors, concludes that there is a single cheap remedy which does wonders; but this remedy he conceals. The only remark made by him deserving notice is, that hectic is generated by the pus which enters the blood; for the disease is partly an affection of the fluids, and not, as has sometimes been supposed, of the solids alone.

255. The Phthisiologia of Morosini was for more than a century a standard work on the subject of consumption, although in all most important matters it was anticipated by the writings of Bennett. There remains, therefore, but a few topics deserving notice. Chalybeate waters are considered by him as preferable to all other means for the prevention of the disease, especially in phthisical constitutions; he directs them to be taken freely, either cold or warm. He considers catarrh to be the most frequent cause of phthisis; and infection sometimes to occur, for he believes that it may be communicated to a bed-fellow. When proceeding from this latter cause, he considers it to be most fatal. He recommends bleeding in the early stage, but views it as fatal in the advanced stages, and opiates for the cough with purgatives, as the alocic tincture. After bleeding emetis are viewed by him as of great benefit, in the first stage, but they ought to be followed by opiates. He frequently prescribes his stomachic pills, consisting of aloes, myrrh, mastich, saffron, cloves, wormwood, nutmeg, calamus, mace, rhubarb, musk, cardamoms, &c. In phthisical and scrofulous consumption he recommends pills of gum ammoniacum, with benzoin and oil of turpentine. But in all forms of phthisis, especially in the more advanced stages, he considers cinnamon the great and general febrifuge. Several forms and complications of consumption are particularised by him as requiring different or additional means of cure. He says that, in asthmaic phthisis, opium is injurious, by increasing the dyspnoea; but that ammonla and the citrate of potas are most useful remedies. In the melancholic and hysterical phthisis, emetics, he avers, act like magic, and opium is particularly requisite. For phthisis complicated with hemoptysis, after venesection and other remedies, he gives the bark in doses of a drachm every four hours. He remarks that calcis may form in the lungs, may lie there a long time inactive, or they act as foreign bodies. Consumption consists, when it ceases, to be of an asthmatic nature. Chlorosis often passes into phthisis, he justly observes, by imperceptible degrees, if not treated by chalybeates and purgatives. When he suspects internal ulceration, he gives from 20 to 30 grains of calomel every third or fourth morning, and the diaphoretic antimony
TUBERCULAR CONSUMPTION.—HISTORICAL SKETCH OF TREATMENT.

at night. Brunner states that he "entertained strong doubts of the propriety of Morton's prac-
tices of giving cinchona in hemoptysis, till he found by experience that it succeeded, where
every thing else had failed." (Young, p. 203.)

256. ETTMULLER recommends emetics early in phthisis, and a diet of milk and raw new egs. BAGLIVI furnishes us with nothing novel, excepting
that he supposes ipecacuan to be the best remedy for this disease, and for all hemorrhages and
discharges. WEPFER furnishes some of the earliest information as to tubercles. In his ob-
servations on diseases of the head, he gives an account of an epidemic consumption at Waldeshut
on the Rhine, where there is a cavern in which mill-stones are dug and brought. The air is
there always hot—even in winter, and a very fine dust floats in it. All the workmen employed
in it become consumptive, if they remain a year, or even a shorter time.

257. STAHL's opinions as to the treatment of phthisis are not worthy of his reputation. His remarks are chiefly directed to the non-efficacy
of most of the means which had been advised up to his time, and many of his observations that
medicines are just. He reproves the use of balsams, ointments, expectorants, cinchona, myrrh, balsam
of sulphur, &c., and confides chiefly in bleeding, and nitre in moderate doses; and ass's
milk, he says, is fit only for ass's. The too general and indiscriminate use of these and other medi-
cines—the universal employment of a medicine because it has been advised, or found useful in one
or even a few cases, is mere empiricism. It is the appropriate exhibition of a medicine to in-
terred pathological conditions, which constitutes rational practice. He remarks that females are
more frequently consumptive than males; but they have a greater chance of escaping its fatal
termination. He considers exercise on horseback, or in a carriage, to be the most beneficial
remedy for phthisis. PUFFER agrees with STAHL as to riding on horseback being most salutary in
this disease, when "without fever or ulcer;" but he adds that "the patient must be a Tartar, and
live on his horse."

258. P. HOFFMANN, the rival of STAHL in reputation, fully discusses the treatment of hectic fever
and phthisis. He remarks that hectic attended by indigestion may often be relieved by an emetic
of ipecacuan, followed by a dose of aloes. If anemorrhcea be a concomitant, bleeding in the feet
and deobstruents, are prescribed by him. If mesenteric disease complicate phthisis, as often
observed in children, warm bathing, nitre, sulphate of potass, and sal-ammoniac are recom-
ended. In all hectic he considers milk a principal remedy, especially woman's milk, ass's
milk, goats' milk, or cows' milk, with manna or conserve of roses, with water. He also
ventures to give the tincture or infusion of roses, cascariilla, cinchona, and nitre. He gives
the murise of potass when the appetite is weak. Bleeding, he says, should be practised with much
caution. He adverts to a patient who was kept alive 18 years being some blood twice a
year, and drinking a decoction of ginseng and saffrafas. The treatment which he more espe-
cially advises for phthisis is somewhat similar to the foregoing. He thinks justly that, where a
predisposition to the disease exists, it may be called

into action by attendance on a consumptive pa-

ent. When a milk diet occasions acidity, he

substitutes whey; with which, or with milk,

mineral waters, or lime-water, may also be

mixed. He considers the best laxatives in phthi-
sis to be manna, magnesia, rhubarb, or seca

tenna. And milk or whey with parsley

seeds, or celery-seeds, to be the best diuretics.
He is not favourable to the use of gum-resins or bal-
sams, if they occasion, or if given during, febrile
action. Myrrh, saffron, copaiba, opium, honey,
wax, spermaceti, and oil are viewed more fa-

vourably. In the young and phlegmatic, small and

frequent bleedings, air, exercise, and warm baths are,

be believes, the best prophylactics. He con-
siders half the cases of consumption to originate

in hemoptysis, and he advises that the bleeding

should not be stopped too soon by astringents.
In advanced cases, bleeding to the amount of an
ounce only, often relieves the breathing. He says

that emetics and strong cathartics are injurious.
He makes favourable mention of issues, and of a

stomachic elixir, composed of myrrh, saffron,
nutmegs, and buck-bean, which is to be taken at
meals, consisting of half a dessertspoonful, and
then an equivalent of 2 spoons of water.
For the colliquative perspiration he gives
nitre and opium in small doses. He often
prescribes also sulphur and diaphoretic antiymony;

and the combination of milk with mineral waters

is much praised by him. It will be seen that
the treatment adopted by the great physician is,
in most respects, of great excellence, and when
employed appropriately to the circumstances,
form, and stage of the malady, by no means in-
favor to any adopted at the present day.

259. Musgrave was the first to point out the

connection of phthisis in some instances with

irregular gout. The treatment he advises is not

materially different from that recommended by

Bennet, Hoffmann, and others. BOERHAAVE

furnishes no information as to the treatment

of phthisis in any way worthy of his great reputa-
tion; his practical judgment appears to have

been overladen by his hypothetical doctrines. The
respectable synopsis of Alles furnishes one very

good suggestion, namely, the propriety of the

liberal use of buttermilk in consumption. He also

believes in the contagious nature of the
disease in certain circumstances favourable to its
operation. WERLEHOF comes to the defence of

cinchona and Morton against the attacks of

STAHL. Doyen in his ancient Physician's Legacy,
appears in his heroic character of buccaneer in the

treatment of phthisis. He advises a frequent

repetition of bleeding in small quantities, horse-

exercise, erude quicksilver in large quantities, a

substance much in fashion at the commencement

of the eighteenth century; and aniseed and
croese maris made into pills with the balsam of
Locatelli, in the morning, and the elixir of vittoli in
the afternoon. He gives also his powder, which
originally contained nitre instead of the sulphate
of potash of the modern powder. He advises

the antiphlogistic regimen.

260. P. Deballot deserves notice for his
having been the first to contend that tubercles in

the lungs constitute the essence of consump-
tion; that they are generally antecedent to ha-

moptysis; and that ulceration of the lungs is
merely an effect and not a cause. He adds

nothing to what has already been stated as to
of the treatment. Juncner, the methodiser of the doctrines of Stahl, furnishes but little information respecting phthisis, and almost none deserving notice, excepting his approval of riding, and his disapproval of warm balsams and ales. Wallis, in his treatise on the symptoms and treatment of phthisis, cautiously concludes, that the quantity of blood is much diminished in heath, and thinks that pectorals and balsamics are injurious, unless they serve as stomachics and diuretics. He prescribes gentle emetics, mild stomachics, riding, pure air, frequent blisters, and a light, digestible diet. Dr. Thomson is in favour of small doses of antimonial wine in consumptions.

261. Dr. Luxiam's reputation induces a desire to know his practice in phthisis. He remarks, that eaten on occasions this disease only when tubercles had previously been formed in the lungs, and that the malady may be fatal before an ulcer is formed. Instead of sweet, oily, emollient, and other substances, which often disagree with the stomach and occasion acidity and diarrhoea, he employs gentle diaphoretics, blisters between the shoulder-blades, a mustard inhalation, the decoction of squills, with guaiacum and strychnia, and inhalations of drying fumigations. He advises those of a consumptive tendency to remove into the country in the spring, and to lose a little blood as a precaution. Rousell's work on glandular disease is also recommended, in recommending a remedy within the reach of most persons, and one of great efficacy when judiciously employed, namely, sea-water, especially when taken internally, warm or cold, according to the constitution. He employs it also externally, at different temperatures.

262. Dr. Mead insists on the intimate connection of phthisis with scrofula, and considers that the use of bark in the disease is indicated by the periodicity of the attendant fever; but he believes it to be injurious when the lungs have become ulcerated. Goats' milk and whey are recommended; and when milk disagrees with the bowels, it may be boiled with roses, pomegranates, and cinnamon, with the addition of water. The fumigations advised by Rousell, change of climate, a voyage to Naples, or Lisbon, are particularly noticed with approbation. Dr. Bryan Robinson praises emetics, especially those with ipecacuan, in haemoptysis, and adds evidence of their effects. Dr. Homberg gives some cases showing the benefits produced by the aluminae chalybeate spring, the Hartfell Spa near Moffat, at an advanced stage of consumption.

263. Dr. Gilchrist addsuces numerous cases showing the great advantage accruing from sea voyages. He considers haemoptysis a consequence of tubercles previously existing, and remarks that there are still tubercles to be resolved, even after ulceration has taken place, and hence the difficulty to give appropriate remedies for every stage in which tubercles may be found. But sailing and sea bathing are the best calculated to fulfil all the indications. On a rocky coast, where the inhabitants live much on shell-fish, he observed consumption decidedly more rare than in the country inland. He considers that the practice in this disease should consist in a proper administration of bleeding, purges, mercury, balsams, diet, sea voyage, and sea air.—The practice of Dr. Marby has been very generally adopted, at least in many of its parts, until modern times. He strongly objects to bleeding in consumption, and recommends a nourishing diet, especially of pork broth, and exercise on horseback, but above all the use correct in concluding, that the quantity of blood is much diminished in heath, and thinks that pectorals and balsamics are injurious, unless they serve as stomachics and diuretics. He prescribes gentle emetics, mild stomachics, riding, pure air, frequent blisters, and a light, digestible diet. Dr. Thomson is in favour of small doses of antimonial wine in consumptions.

264. There are few topics connected with the treatment of phthisis more important than that respecting the employment of opium, and to this Thalies has devoted much attention, in a prolix and discursive work, in which the general treatment of the distempers is applied to the particular. He considers opium to be useful in the first stage, but to be injurious afterwards. He thinks that it is not even a palliative. He, however, gives it in enemata with decoction of bark and milk, for the palliation of the colliquative diarrhoea, and not that it is useful in small doses when the cough is violent, for which also he gives the syrup of poppies. He recommends Plummer's pill, ammoniacum, soap, squills, and honey, milk diet, milk with lime-water, emulsions, and farinaceous substances. The works of Monro give rise to no precise information as to either the morbid anatomy or the treatment of pulmonary consumption, beyond what was previously known. Of the other contemporary writers on medicine there is none who gives any information respecting the treatment of consumption, deserving notice, until we arrive at the works of Sir John Ffingslie, Donald Monro, and others.

265. The observations of Sir John Ffingslie deserve the high estimation in which they have always been held. In recent coughs he gives, after bleeding, a change of climate, a voyage to Naples, or Lisbon, to form an emulsion; and at night laudanum with oxymel of squills, or gum ammoniac. When the symptoms assume the form of hectic, he repeats the bleeding, recommends low diet, and the employment of setons or issues, which he justly considers still more beneficial than bleeding. If thirst or heat be great, acidiulatated drink, or buttermilk, without animal food, are advised. To check the sweats he uses sulphuric acid, or lime-water, conserve of roses, air, exercise, a milk and vegetable diet, and where there are debility and lowness of spirits, the bark is recommended. Donald Monro appears to have adopted the practice of Pringle in phthisis. He has recourse to bleeding when there is pain, and to cathartics when neither pain nor difficulty of breathing is experienced; he does not wish us to forget that bleeding, as far as is possible, is the object of treatment in phthisis, and that advice should be given by the whole profession.
TUBERCULAR CONSUMPTION. — HISTORICAL SKETCH OF TREATMENT. 1141

water, or Morton's balsamic pills, the flames of balsamic herbs, the waters of Bonnes or seltzer, or lime-water mixed with milk, riding, issues between the shoulders. For the consumption produced by hard study, he prescribes camphor with Hoffmann's anodyne, baths, frictions, change of air, horse-exercise, and generous wine. Linnæus suggests the use of the lichen pulmonarius in phthisis. The Lichen Islandicus was known to earlier writers, according to Dr. Young, although it is not mentioned by Linnæus. Mr. Read lauds a residence in a cowhouse in cases of consumption, and says that it is preferable to any fumigations. The recommendation of a medicine called the decoction of a thousand flowers, which was much used from two to three centuries ago for the different forms of consumption, is more rational than this singular residence. This decoction, or infusion, as sometimes prepared, was made from the recent dung of cows, whilst feeding in open pastures, warm or cold water being mixed with it, and allowed to stand a considerable time, and the clear fluid being poured off for internal use. The things Spanish was thus partially extracted, and employed as a stomachic.

267. The works of Herberden, Sauvages, and Fothergill, furnish no additions to the method or means of treating phthisis already known. Strenuea is extravagant in its praises of hemlock in this disease. Van Swieten, in his commentaries on the aphorisms of Boerhaave, observes that persons exerting their voice in their professions are more liable to hemoptysis than others; and that Molière died of an attack of this disease immediately after performing his "Malade Imaginaire" for the fourth time. He believes in the communication of phthisis by infection, and considers that an hereditary disposition to the disease does not necessarily imply its actual existence. He approves of camphor as prescribed by Avicenna (§§ 247.), and of the treatment adopted by Pinelle. He praises the use of milk, small but frequent bleeding, horse-exercise, the cautious employment of cinchona, and of opiates. For relief of the diarrhoea, he directs an enema of a drachm of turpentine, rubbed down with yolk of eggs, adding half an ounce of wine, and four ounces of new milk.—The treatment recommended by Macbride is, in most respects, the same as that already so frequently noticed, namely, gum ammoniac, soap, and ammonialisol, early in the disease; gentle emetics to promote expectoration and relieve dyspnoea; bark, in some cases, goat's whey, asses' milk, buttermilk, seltzer, Bristol, or Malvern waters; riding, and especially sea-voyaging, setons, or issues, &c. For hemoptysis, he directs bleeding, opiates, and demulcents. Wistarinaem disapproves of fumigations, as prescribed by Bennett and Mixad, but thinks that the steam of hot water containing vinegar of squills may be inhaled with advantage.

268. Dr. James Sims, the founder of the Medical Society of London, is favourable to emetics, to sulphur, and to cinchona, suitably employed. Taylor's "Individuals," but he considers tar pills to be preferable. The following remarks are correct:—Females not uncommonly have a respite from consumption when they marry, but sink under the disease after having had two or three children. The catamenia may remain natural till the last stage, but this, I may add, occurs only occasionally, and chiefly in the more chronic and protracted cases. Schonheyder employs the decoction of Iceland moss, especially in phthisis consequent on measles, or after the removal of inflammatory symptoms. To this very judiciously gives the bichloride of mercury in the infusion of cinchona, with Iceland moss, and a milk diet, in phthisiac consumption.—Dr. Moses Griffith is deserving of notice, chiefly for his recommendation of chalybeates in consumptions, and more particularly for his Mixtura Perri Composita. This mixture is, however, varied by him according to the circumstances of the case; adding nitre in young subjects and recent cases, myrrh at a more advanced stage, and when there is more debility. He further advises a diet of asses' milk, or skimmed milk, puddings, rice, potatoes, and a little light animal food, once a day, and above all, smalt-broth, or snails boiled in milk. Linne reports favourably of the Hypericum perforatum, in haemorrhagic and ulcerous phthisis, a handful of the tops of the plant being made into a decoction and used in the dosing Spanish: this was thus reduced down to one-third, and an eighth taken morning and evening.

269. The treatment adopted by Cullen for phthisis was generally followed in this country until early in the present century. When expectation of purulent matter, with hectic fever, is present, he believes that ulceration exists. He views cattarrh as rarely a cause of phthisis in persons not predisposed to this disease, but it ought not to be neglected. Spasmodic asthma not unfrequently terminates in phthisis. In two cases of the expectation of chalybeates, the patients recovered by the aid of milk diet, &c. Consumption from hemoptysis is less universally fatal than other forms. "Haemoptysis is not always followed by ulceration, nor is ulceration always attended with hectic. Pregnancy retards the symptoms, but they generally recur and become fatal soon after childbirth." In the haemorrhagic form of the disease he thinks the acetate of lead dangerous, and chalybeates and cinchona improper, as tending to increase the phlogistic diathesis, and as having been found injurious in his practice. He prefers evacuations of all kinds, a low regimen, and blisters to the breast or back, followed by issues. Sea-water, and other mineral waters are wholly useless, and mercury is prejudicial. Milk is a chief remedy; and violent exercise, and the extremes of cold and heat, are to be avoided. He thinks that sea air is desirable only for its moderate temperature; that the balsams, myrrh, &c., have sometimes done harm; that bark increases the phlogistic diathesis, and even when it relieves for a time, the symptoms speedily return; that acids are useful, especially vegetable acids; that opiates are necessary for allaying the cough, but they often increase the sweats; that demulcents frequently disagree with the stomach; that the diarrhoea requires astringents and mucilages, and that all purgatives are dangerous, but ripe fruits are often both agreeable and useful. Dr. M. Bart records cases illustrating the connection of tuberculous phthisis with serofula, and the successful treatment of the former by small doses of corrosive sublimate, and by a diet of soup, eggs, and vegetables.
270. Stoll offers some judicious observations, although others are more open to objections. For tuberculous hemoptysis he advises small and repeated doses of bland medicines; acid and nitrous drinks, and afterwards loben, polygala senega, or cinchona. For hectic diarrhoea he gives the powder of the root of arnica. He disapproves of balsams, bark and astringents, where there is any inflammatory complication.—Bennett strongly recommends the Iceland moss in phthisis. When its tonic qualities are not required he directs the bitterness to be extracted by previous maceration.—Dr. Mudge employs the inhalation of medicated vapours for consumption. He believes hemoptysis to result from the obstruction caused by tubercles; and for this state of the disease he advises nitre in solution, a moderate bleeding, and emetics; for cough the inhalation of emollient vapours, the ammonium with laudanum, or half a drachm of the anisated balsam of sulphur, a very large scapulatory issue, if these fail, and these fail, the use of small issues, and advises them to be large and efficient—a recommendation agreeable to my experience.

271. Dr. Simmons notices the form of consumption produced by dry-grinding, or by breathing the minute particles of sandstone and iron. He considers the practice of bleeding to have been carried too far by Doven. He prescribes nitre and camphor, myrrh with spermaceti; and oranges and ripe fruit in preference to sulphuric acid. Setons and issues, he says, are useful, opiates mischievous, and ripe fruit and antiseptics are the best remedies for diarrhoea. A little animal food, plainly dressed, may be allowed if much desired. Change of air is advised; but, he justly adds that migration to a warm climate, late in the disease, merely hastens death. Emetics of sulphate of copper, twice or thrice a week, in the early stages, preceded and followed by a draught of water, are also given with the vain hope of dispensing the tubercles.—The observations of Home, Duncan, and Reid furnish little or no information. The last named physician advised chiefly the exhibition of injured and treating phthisis, morning and evening, and considered sea-voyaging beneficial, mainly by producing nausea and vomiting. Verily his treatment seems to have been as bad as the disease. Borshein again thinks emetics injurious, and balsamic remedies hazardous; but he approves of bark in incipient cases, of camphor, and of balsam of tolu and turpentine in advanced stages. Pouteau advises, when pain is experienced, bleeding, and cupping, and blisters.

272. Dr. Stark's posthumous observations contain the earliest correct account of the anatomy of tubercles. He is favourable to bleeding in the early stages, to oleaginous and demulcent medicines, and to vinegar of squills, &c., when cough and dyspepsia are urgent. Ravelin's views as to the treatment of phthisis are in some respects heterodox. He is more correct in recommending speciecaha in the catarrhal complications of the disease. He considers gums to be preferable to emulsions; and the preparations of cascarilla to be appropriate for the sweats and for diarrhoea. Syrup of tolu with ptisans; and myrrh, camphor, and a little opium every night, are very generally prescribed. He praises opium in large doses for hemoptysis; and the mineral waters of Cauterets and Bonnes for convulsions. Dr. Withering, in 1785, in his account of the snowglove, notices the recommendation of this mineral for the treatment of phthisis in consumption, and states that he found it of advantage in several cases when it was given in a decided manner. Dr. Darwin, however, is doubtful of its good effects; and Sir G. Baker is of opinion that its influence in phthisis is owing to the sickness. When its tonic qualities are not required he directs the bitterness to be extracted by previous maceration.—Dr. Mudge employs the inhalation of medicated vapours for consumption. He believes hemoptysis to result from the obstruction caused by tubercles; and for this state of the disease he advises nitre in solution, a moderate bleeding, and emetics; for cough the inhalation of emollient vapours, the ammonium with laudanum, or half a drachm of the anisated balsam of sulphur, a very large scapulatory issue, if these fail, and these fail, the use of small issues, and advises them to be large and efficient—a recommendation agreeable to my experience.

273. Sir G. Blane considers the best climate for the consumptive to be between 30° and 40° north latitude. Voelz prescribes the vegetable acids with gum arabic; and, for phthisis after fevers, the taraxacum, bitter extract and horseradish, or the cold infusion of cinchona with rhubarb, if inflammatory symptoms be absent. The cold infusion of bark he gives most frequently with acids or nitre, or made with whey, and preferably during the remissions of the hectic. He agrees with Sim's as to the use of oysters as an vegetable. He Q. Darwin considers emetics unsafe in phthisis; he gives bark with sulphuric acid for the sweets; spa water with milk in preference to saltier water; and the senega when the expectation is difficult. Dr. Mosley believes that England furnishes change sufficient for an invalid, but that a voyage to Madeira early in the disease may be of advantage. For haemorrhagic phthisis, and pulmonary oppression he prescribes a vitriolic solution with the sulphates of zinc and alumina as an emetic, instead of bleeding, followed by a sea voyage.

274. Dr. May states that, in a well-marked case of phthisis in a young person of a scrofulous constitution, the patient took laudanum night and morning, an ippecacuanha emetic when the stomach was loaded, and cinchona; and that the diet consisted of soup, meat, wine, porter, brandy and water, eggs, oysters, &c. with proper condiments. Swinging was employed twice daily, and horse-exercise completed the cure. A similar case was published by Dr. Kentish. I recollect meeting Dr. May in 1820. He argued strongly in favour of his tonic and nourishing method of treating phthisis, morning and evening, and considered sea-voyaging beneficial, mainly by producing nausea and vomiting. Verily his treatment seems to have been as bad as the disease. Borshin again thinks emetics injurious, and balsamic remedies hazardous; but he approves of bark in incipient cases, of camphor, and of balsam of tolu and turpentine in advanced stages. Pouteau advises, when pain is experienced, bleeding, and cupping, and blisters.

275. The second volume of the "Medical Inquiries" of Dr. Rear of Philadelphia, contain some of the most important observations on consumption which appeared towards the close of
the last century. He was himself subject to consumptive symptoms during a considerable portion of his life,—a circumstance which imports nothing against the validity of his conclusions. He recommends digitalis upon the first indication of the disease, or as soon as heat in the hands, weakness of the eyes on waking, dryness of the feet, inactivity, and other slight febrile symptoms appear, the patient to have recourse to a more active life, with bathing, baking, and swimming. When the patient is in a state of bloody expectoration, he directs frequent bleedings, and where bleeding cannot be employed, emetics and milk diet. In the last, or typhus stage, as he terms it, he considers that a temporary benefit is derived from balsams, homeopathic vegetable tonics, bitters, cinchona, &c., the diet being now stimulating and nutritious. He believes damp situations injurious in all states of the disease, and a high, dry, and temperate residence in the country most beneficial. He advises also flannel always to be worn next to the skin, the clean clothes of the poor, or the smoke of resin to be inhaled, opium to be given in small doses during the day, and more largely at night, and repeated blisters and small issues to be employed. He admits of a moderate exercise of the lungs in speaking, reading and singing; and a gradually increased exercise of the body, especially of the limbs.

276. Dr. GREGORY of Edinburgh in his lectures considers mercury injurious; cinchona of little use, and myrrh of less. The mineral acids he views as palliative only, and as inferior to the citric acid. Emetics are sometimes useful, even without operating powerfully; sulphur is liable to be too laxative, but beneficial nevertheless; and purgatives hazardous as either inducing or aggravating the diarrhoea.—Dr. FERRIER finds digitalis with change of air of service in the mucus consumption (chronic bronchitis), and in checking incipient phthisis, when the patient is too weak to bear evacuations. The pulmonary means, so much and so silently vaunted at that time, and like other means puffed, with their authors, into undeserved notice much more recently, he justice considers quite undeserving. Dr. C. photographic and chemical medicines into practice, about the end of the last century. He prescribes the sulphurate of potass, and powdered charcoal, in the florid states of consumption, and gives a draught of each of these, four or five times a day, in warm water, with the effect of promoting expectoration and improving the other symptoms. I question, however, the ultimate good arising from medicines which "promote expectoration," as I have too frequently seen them promote other more unfavourable symptoms.

277. In the writings of DARWIN, in which there is a mingling of hypothesis, fancy and poetical imaginings, with ill-ascertained experience, I find nothing on the treatment of phthisis deserving notice, or at least nothing worth attention which had not been previously advised by many of his predecessors.—J. PRANCE professes himself an advocate for the tonic and nutritious treatment in phthisis proposed by SAVALDORI, MAY, and others, though with much more moderation in the degree; palliating the urgent symptoms by opium, and endeavouring to relieve the debility by cinchona, bichen, milk, wine, exercise and nutritious food— a treatment, however, by no means admitting of general adoption. — Dr. BARTON mentions the Arum triplicium boiled in milk as a remedy in phthisis, states the disease cured by digitalis; and that he finds more benefit from emetics of sulphate of zinc, than from other means.

278. Dr. FOWLER and Dr. FERRIER relate cases of consumption cured by digitalis given as decoc- tions or infusions; but it is hardly possible that more benefit was imputed to the medicine than it really deserved, as most of the cases were characterised chiefly by haemoptysis, and as those are often attended by prolonged periods of amendment. That it is, however, followed by some degree of benefit, especially early in the hematoptical form of the malady, appears from the testimony of BEDDOES, MORESMAN, MACLEAN, SHERWIN, and others, although this position is denied by Dr. BREE, Dr. MACKENZIE's success with digitalis may be attributed chiefly to the very large doses, and the early period of the disease in which he prescribed it. BUNSEN in his researches employs chiefly aconite, hemlock, henbane, and dulcamara, combined with either ipecacuan, cherries mineral or honey of squill. He prefers the leaves of aconite to the extract, and gives two grains every two hours, increasing the dose to a drachm daily. DR. BEDDOES insists upon the propoerty of confusing the phthisical patient to a temperature varying only from 60° to 65°, and believes that the muriate of lime is sometimes of service.

279. Dr. HERBERDEN considers asses' milk to be of use in allaying the fever; decoction of bark and sulphuric acid in relieving the sweats; opium in quieting the cough and favouring sleep; bleeding to the amount of five ounces only, when pain is urgent; and the application of a blister when the pain is obtuse. He advises a vegetable diet chiefly, and the purest water for drink.—Dr. Thomas recommends an emetic every second or third day, especially in the early stage. GRIFFITH'S iron and myrrh mixture, and digitalis. Dr. Trotter is favourable to cinchona and sulphur, and to digitalis with opium. Dr. WILSON conceded several effects of medical medicines into practice, about the end of the last century. He prescribes the sulphurate of potass, and powdered charcoal, in the florid states of consumption, and gives a draught of each of these, four or five times a day, in warm water, with the effect of promoting expectoration and improving the other symptoms. I question, however, the ultimate good arising from medicines which "promote expectoration," as I have too frequently seen them promote other more unfavourable symptoms.

280. Dr. BADDAM, in 1808, was the first to distinguish between endemic and chronic bronchitis, and consumptive phthisis, the former having been generally viewed as varieties of pulmonary con-
TUBERCULAR CONSUMPTION.—HISTORICAL SKETCH OF TREATMENT.

...sion, and thus confounded with the tuber-
cular disease. A large proportion of the recoveries of cases which had been considered tubercular, was, in the hands of skillful practitioners. Several writers at this period added nothing to our knowledge, or placed before us the "crumb his coctum," or rather decoct coctum, of their predecessors. Russell expresses a favourable opinion of bark, cumbrums, chamois, sulphuric acid, and iron, with hem-
lock. But these require dilution and mollification, as to the casual agents which may be individually prescribed. He considers the virtues of hemlock to be much overrated. Both he and Thomson state the mu-
riate of lime to be without any efficacy. In the more purely scrofulous phthisis, he considers issues to be decidedly beneficial, and sulphuric acid and salines as preferable to cinchona in the early stage. Barton and others in America em-
ploy the super-acetate of lead with ipecacuan and opium in the haemoptic form of phthisis.

281. The remarks of Dr. Park are upon the whole judicious. He advises the pain in phthisis to be allowed to remain unrelieved, emetic-
ties to be given chiefly in haemoptysis, and without informing the patient, ipecacuanha being pre-
ferred; and mild diaphoretics in an early period. He considers balsams of use only when expecto-
ration is checked by debility; myrrh occasionally of service as a slight tonic and sedative; hem-
lock to be preferable to opium in palliating the cough without occasioning sweats; cicuta and the seeds of hyoscyamus to be often useful; and digitalis to do more harm than good. Asafetida is recommended for flatulence and as an expec-
torant. In the last stage, emetics and other means are quite ineffectual, or palliative merely.

—The work of Portal, although interesting at the time it appeared, contains very little of importance in respect of treatment. He considers the mildest food the best, and particularly new-
laid eggs; and issues, setons, and mezoxs, of ser-
vice. —Dr. Buxton furnishes additional evidence to that adduced by Beddoes in favour of a regu-
lated temperature in phthisis, of from 60° to 65°. Dr. Shearman notices the connection of con-
sumption with amenorrhea, and observes that Gynecia hanumatre has been more successful in females than in males, owing to this connection. There is much truth in this: early in the disease this mixture is advantageously conjoined with the compound decoction of aloes and comosum, and even in more advanced stages, if it do not increase the severity of the cough.

282. M. Bayle very justly referred many of the cases of imputed recovery from phthisis, to the circumstance of chronic bronchitis, or chronic pulmonary catarrh having been mistaken for phthisis; and he described, with greater preci-
sion than heretofore, the structure of the tubercular deposits, and the pulmonary and the associated lesions. The granulated form of this writer is merely the earlier stages of the disease, excavations not having taken place. In this state he advises, according to the features of in-
dividual cases, composing and emollient medi-
cines, occasionally bleeding, blisters, and issues; aconite, hemlock, henbane, nightshade, and opium, and, where the expectoration is very copious, balsamic and resinosous medicines. In the state of oeleption, he employs medicated vapours, and external draughts and revulsants of various kinds. In cases complicated with chronic bron-
chitis or catarrh, the lichen, with diaphoretics and balsams, is prescribed; or with bark, when there are well-defined secretions. In the expectation require lemonade or orange-
ade, and bleeding if the pulse be hard, blisters, if soft. As prophylactics, he recommends trav-
elling, voyaging, change of air and climate, nutritious diet, anti-scorbatics, tonics, alkalies, muriate of ammonium, dittany, for incipient cases, and for cases in which the patient is overthrown, a sea voyage, exercise, the sulphurated waters of Bonnes, Caul et et, Bagnères, or Mont d’Or; and later in the disease, mild tonics, as the lichen, syrup of cinchona, &c.

283. Dr. Wells contends that phthisis is much less prevalent in marshy countries and districts where agues are endemic, and advises that consumptive patients should be removed, at least for some time, to these places. He quotes several authorities and statistics, by both which the subject is placed in exaggerated terms of view: It is well established that the malarial situations are beneficial in either the early or the advanced stages of phthisis; at least the matter should be further investigated, as well as the assertion that places wherein ague is en-
demic, are free, or nearly free, from phthisis inasmuch as the position is controverted by several more recent writers, although contended for by Marshall, Wekes, Harrison, and others to-
wards the close of the last century and at the commencement of the present.

284. Dr. Roberts has endeavoured to discover a more effectual remedy for consumption amongst the active mineral salts and other substances, than those hitherto employed. He has, however, only to record the failures of his experiments, with the nitrate of silver, superacutetate of lead and opium, sulphate of zinc, oxalate of zinc, alone or with myrrh; white oxide of manganese (10 grains); arsenite of potass; black oxide of cobalt (one to four grains); ammoniated copper, muriate of baryta, nitric acid, phosphoric acid, aconite, henbane, stramonium, belladonna, and toxocodendron.

285. Dr. A. Duncan gives the results of his long experience in the treatment of phthisis. He considers haemoptysis as often a salutary occurrence early in the disease; bleeding with low living to have hastened death in many cases; emetics to be of use in promoting expecto-
ration, but to be useless as respects the cure of the disease; and blisters to be of service in most forms of the malady. He believes that vegetable acids are more beneficial than the mineral or sanguine; that digitalis is of little use, and sea voyages are counteracted by the inconveniences and risks attending them; that bark, myrrh, lichen, or these with hemlock, are sometimes of service in scrofulous cases, but that the pneu-
matic practice is altogether unsuccessful; that the diarrhoea may be moderated by mucilaginous fluids and broths, melted jellys, rice, cattchu, opium, &c.; that the inappetite of the com-
mon lettuce is one of the best substitutes for opium, and that the patient should take asses' milk, wear flannel next to the skin, and have walking and riding exercise. —Dr. Southby has remarked upon the frequency and infrequency of phthisis in dif-
ferent countries. He is in favour of the use of
issues, of digitalis for haemoptysis, of a regulated temperature, by means of a stove from 60 to 65°, of riding, sailing, and swinging, and of change of air, at an early stage, to Valencia, Hères, &c.

Dr. Thomas Young, in his able and learned work on Consumptive diseases, has given an interesting account of the treatment of these diseases, and a full digest of the means employed for this purpose in this country during the first quarter of the present century; and until the diagnostic method of Laennec and the pathological and numerical disquisitions of French writers allured the minds of practitioners to the neglect of rational therapeutical doctrines, Dr. Young considers bleeding an important remedy at an early period of the malady, for the removal of inflammatory and congestive symptoms, and for diminishing the suppuration and debility consequent on them. From six to twelve ounces of blood, he remarks, may be taken away with safety in every incipient case, and the operation may generally be repeated with advantage three or four times, at proper intervals; but to do more than this is not judicious, as the blood is then the only single source, however laudable in proper circumstances, is not to be recommended in the ordinary routine of practice. Dr. Young was himself bled twice, by the direction of his uncle Dr. Brocklesby, and was in favour of small bleedings, to the extent of three or four ounces — locally, when there is pain in any part of the chest. He advises purgatives at an early stage, and considers that fears of promoting the diarrhoea by them at this period should not be entertained. He justly views sulphur as an excellent aperient in the disease, and especially when complicated with hemorrhoids. Dr. Young also recommends emetics, and prefers ipecacuanha, especially in cases of hemoptysis, combining it with aperient, or other means, according to circumstances. On sorbifacients, especially digitals, merrcurials and alkalies, he places very slight reliance, although they may be prescribed in some circumstances of the disease with advantage. Episiptics and issues are viewed by him much more favourably. He considers that the tendency to night sweats is not a just reason against the use of sudorifics, especially Dover's powder and cold water. Its other effects, in all cases, he has little faith, although ammoniacal, squills, senega, myrrh, and ipecacuanha may be employed with benefit in some cases, in conjunction with hemlock and other palliatives. Denulcents and nar- cotics are prescribed by him in circumstances indicating their use, sometimes with balsams, the benzoic acid, &c. Of astringents, when required to moderate the secretions of the skin and of the intestines, the sulphuric acid is considered the best, especially when combined with aromatics and opiates; but he is also in favour of catechu, kino, the extract of logwood, with chalk mixture, or the compound powder of chalk.

287. Dr. Young believes enema is the most important tonic, and both its advantages and inconveniences to have been exaggerated. He has known it decidedly beneficial at the commencement of the disease, and he has never observed that it increased the hectic symptoms at any period. Besides the powder, and the decoction, he has employed the cold infusion with Seltzer water, in his own case, as well as in others. He has had little experience of chaly-
more immediate or early effects is all that can be expected from the latter: the one is positive, for the causes have not existed or acted; the other is negative, in that the causes that now present, have probably acted and produced their more immediate effects, the means of counteraction or of arresting these effects either succeeding or failing, as numerous circumstances may determine. Prevention thus may be divided into,—first, that which consists of the causes of all the causes of the malady; and, second, that which attempts the counteraction, or the removal of their more direct and immediate effects, before the malady is fully developed.

291. A. The Efficient Prevention of Phthisis consists in the avoidance and removal of the causes which predispose to, and directly occasion, the malady. Those which affect one or both parents, or which operate during the earliest epochs of childhood, have generally produced their effects upon the constitution before profession advice is needed, and the transgressions of the parent have already injured the offspring, and the scrofulous taint has either been communicated to, or generated in, the child, before efficient measures of prevention could be instituted.

The remarks which I have offered on the prevention of Scrofula (see §§ 148. et seq.) apply equally to this disease, whether it be hereditary or occasioned by the habits or the diseases of the parents, or by the management of infancy and childhood, has been produced, the radical and complete prevention of the malady can then rarely be effected, the best efforts to prevent being merely conditional or uncertain. It is only by the avoidance of those causes which I have arranged under the head of Causes appertaining to one or both parents, aided by the removal of those which usually act during the earliest epochs of life, that the efficient or certain prevention of this disease can be expected.

292. B. The Conditional Prevention of Phthisis, although uncertain, should not be neglected. Where the predisposition, arising from either the constitution or the health of the parents, already exists prevention may be hoped for, but it cannot be insured.—a. During Infancy and Childhood the Hygienic precautions which were offered when treating of Scrofula (§§ 148. et seq.) are even more urgently required when tuberculosis consumption has appeared in the family of either parent, or when the causes mentioned under the first class of the arrangement have injured the constitution of one or both parents. For children thus circumstanced, a dry, pure, and mild air, considerably elevated above the surface of the sea; frequent change of air; clothing suited to the temperature and season; exercise in the open air; light digestible food, with special attention to the digestive functions; a milk, farinaceous, and vegetable diet, with a moderate proportion of wholesome animal food, as childhood advances; but the milk of a healthy nurse, asses milk, &c., during infancy, as long as present, have probably acted and produced their more immediate effects, the means of counteraction or of arresting these effects either succeeding or failing, as numerous circumstances may determine. Prevention thus may be divided into,—first, that which consists of the causes of all the causes of the malady; and, second, that which attempts the counteraction, or the removal of their more direct and immediate effects, before the malady is fully developed.

293. b. During Infancy and Adult Age, the causes of phthisis which have been noticed as most frequently operating in these epochs of life (§ 184. et seq.) should be carefully avoided, especially those which relate to schools, sleeping apartments, &c. A strict surveillance ought to be instituted over youths of both sexes in order to prevent masturbation, and as soon as this vice is detected, its enormity should be represented to the delinquent, and measures taken to prevent the mental contamination from extending to others. The sleeping rooms should be well ventilated; but the transgressions of the parent have already injured the offspring, and the scrofulous taint has either been communicated to, or generated in, the child, before efficient measures of prevention could be instituted.

The remarks which I have offered on the prevention of Scrofula (see §§ 148. et seq.) apply equally to this disease, whether it be hereditary or occasioned by the habits or the diseases of the parents, or by the management of infancy and childhood, has been produced, the radical and complete prevention of the malady can then rarely be effected, the best efforts to prevent being merely conditional or uncertain. It is only by the avoidance of those causes which I have arranged under the head of Causes appertaining to one or both parents, aided by the removal of those which usually act during the earliest epochs of life, that the efficient or certain prevention of this disease can be expected.

292. B. The Conditional Prevention of Phthisis, although uncertain, should not be neglected. Where the predisposition, arising from either the constitution or the health of the parents, already exists prevention may be hoped for, but it cannot be insured.—a. During Infancy and Childhood the Hygienic precautions which were offered when treating of Scrofula (§§ 148. et seq.) are even more urgently required when tuberculosis consumption has appeared in the family of either parent, or when the causes mentioned under the first class of the arrangement have injured the constitution of one or both parents. For children thus circumstanced, a dry, pure, and mild air, considerably elevated above the surface of the sea; frequent change of air; clothing suited to the temperature and season; exercise in the open air; light digestible food, with special attention to the digestive functions; a milk, farinaceous, and vegetable diet, with a moderate proportion of wholesome animal food, as childhood advances; but the milk of a healthy nurse, asses milk, &c., during infancy, as long as present, have probably acted and produced their more immediate effects, the means of counteraction or of arresting these effects either succeeding or failing, as numerous circumstances may determine. Prevention thus may be divided into,—first, that which consists of the causes of all the causes of the malady; and, second, that which attempts the counteraction, or the removal of their more direct and immediate effects, before the malady is fully developed.

293. b. During Infancy and Adult Age, the causes of phthisis which have been noticed as most frequently operating in these epochs of life (§ 184. et seq.) should be carefully avoided, especially those which relate to schools, sleeping apartments, &c. A strict surveillance ought to be instituted over youths of both sexes in order to prevent masturbation, and as soon as this vice is detected, its enormity should be represented to the delinquent, and measures taken to prevent the mental contamination from extending to others. The sleeping rooms should be well ventilated; but the transgressions of the parent have already injured the offspring, and the scrofulous taint has either been communicated to, or generated in, the child, before efficient measures of prevention could be instituted.

The remarks which I have offered on the prevention of Scrofula (see §§ 148. et seq.) apply equally to this disease, whether it be hereditary or occasioned by the habits or the diseases of the parents, or by the management of infancy and childhood, has been produced, the radical and complete prevention of the malady can then rarely be effected, the best efforts to prevent being merely conditional or uncertain. It is only by the avoidance of those causes which I have arranged under the head of Causes appertaining to one or both parents, aided by the removal of those which usually act during the earliest epochs of life, that the efficient or certain prevention of this disease can be expected.

292. B. The Conditional Prevention of Phthisis, although uncertain, should not be neglected. Where the predisposition, arising from either the constitution or the health of the parents, already exists prevention may be hoped for, but it cannot be insured.—a. During Infancy and Childhood the Hygienic precautions which were offered when treating of Scrofula (§§ 148. et seq.) are even more urgently required when tuberculosis consumption has appeared in the family of either parent, or when the causes mentioned under the first class of the arrangement have injured the constitution of one or both parents. Prevention thus may be divided into,—first, that which consists of the causes of all the causes of the malady; and, second, that which attempts the counteraction, or the removal of their more direct and immediate effects, before the malady is fully developed.

293. b. During Infancy and Adult Age, the causes of phthisis which have been noticed as most frequently operating in these epochs of life (§ 184. et seq.) should be carefully avoided, especially those which relate to schools, sleeping apartments, &c. A strict surveillance ought to be instituted over youths of both sexes in order to prevent masturbation, and as soon as this vice is detected, its enormity should be represented to the delinquent, and measures taken to prevent the mental contamination from extending to others. The sleeping rooms should be well ventilated; but the transgressions of the parent have already injured the offspring, and the scrofulous taint has either been communicated to, or generated in, the child, before efficient measures of prevention could be instituted.

The remarks which I have offered on the prevention of Scrofula (see §§ 148. et seq.) apply equally to this disease, whether it be hereditary or occasioned by the habits or the diseases of the parents, or by the management of infancy and childhood, has been produced, the radical and complete prevention of the malady can then rarely be effected, the best efforts to prevent being merely conditional or uncertain. It is only by the avoidance of those causes which I have arranged under the head of Causes appertaining to one or both parents, aided by the removal of those which usually act during the earliest epochs of life, that the efficient or certain prevention of this disease can be expected.
and, although it has been controverted by several writers, yet I believe, from several facts with which I am acquainted, that it is not quite devoid of truth.

206. In this, as well as in other periods of the disease, the clothing, especially that worn nearest the skin, should be warm, and the best suited to the preservation of the functions of this part of the frame. With this object flannel ought to be worn during the night and day; and the dust which females should be sufficiently high to protect the upper regions of the chest and the neck. Close cinctures of the chest, and steel supports in corsets are injurious. Due attention ought always to be paid to the digestive and excreting functions, and to the state of the uterine discharges; which are often more or less disordered in the states of the disease now being considered. In many instances cod-liver oil may be of service; in others, as well as in these, sulphurized or chalybeate springs, or a course of the one following that of the other. The treatment of individuals for males is decretum aloe compositum, in varying proportions, according to the state of the bowels, are often of service, especially when the pulse is languid, the catarrha scanty or difficult, and when the cough is not increased or rendered hard or dry by these medicines. In these cases flannel drawers, in addition to the other articles of flannel clothing, and woolen stockings should be worn. In other circumstances, or when the natural secretions and excretions are not suppressed, the infusion, or a weak decoction, of cinchona, with a mineral acid; or other tonic infusions, with aromatics, &c.; or the tinctura murmariæ ferris, either without or with the preparations of Calumba and an increased quantity of the acid, may be prescribed, and may even be made the vehicle on the surface of which the cod-liver oil may be taken. Confined positions of the body, the labours of the deck, and close application to either study or business, ought to be avoided; and a due restraint should be placed on the instinctive desires and passions. Mental and physical occupations ought to be pursued as much as possible in open air; and the temperature, and in a temperature never lower than 60° nor higher than 70°; and should not be such as to fatigue, but such as moderately or pleasantly engage the mind and body.

297. In this state, as well as in the preceding, and more particularly when the predisposition is marked, or the tubercular excaehia manifest, warm or tepid salt-water bathing, or sponging the surface of the body daily with a warm, tepid, or cold solution of salt—the temperature and strength of the solution varying with the state of the patient and the effects produced—is often beneficial; but this practice should always be followed by rubbing the surface smartly with a rough towel, and by the constant use of flannel nearest the skin. Various medicated fluids or lotions have been advised as washes for the chest and neck, in the circumstances now being considered, as well as in the first stage of the disease. Of these, however, the most deserving notice are, a weak solution of the nitro-muramic acid, a weak solution of the pyrogallic acid, and tar-water, varying in strength with the circumstances of the case. This last lotion has been employed only.
TUBERCULAR CONSUMPTION.—TREATMENT OF FIRST STAGE:

by myself, the temperature of it, as well of the others, being varied according to the feelings of the patient and the state of the air. Friction of the chest is also to be avoided. The patient should always follow a recourse to either of these.

298. iv. Treatment of the usual Form of Pneumonia.—Treatment of the First Stage of this Form. The imminence of tuberculous consumption may be viewed almost in the same light as the commencement of this stage; and the treatment advised for the former is altogether applicable to the latter, with various additional means adapted or modified to the circumstances of individual cases. When this stage has commenced, as indicated by the symptoms (§ 187, et seq.), the question is no longer, Are tubercles already formed? This must be answered in the affirmative. But their development may be delayed or prevented by judicious treatment; or their absorption may even be procured, although this is a doubtful or rare occurrence. The great principle of treatment in such cases, as well as when the disease is merely threatened (§ 295. et seq.), is to develop the powers of life, and increase the vital resistance to the further advance of the malady, without producing or augmenting febrile symptoms:—1st, By diet and regimen—by Hygienic. Medical. By medical treatment, the selection of means belonging to each of these heads, appropriately to the peculiarities of the case, will frequently promote the assimilation of the chyle globules and of the colourless globules of the blood, by supporting or developing the powers of life.

299. A. The Food and Regimen of the Patient are of the utmost importance in this stage.—The food has always been discussed, questioned, dogmatically prescribed, and often pertinaciously persisted in, according to the doctrines of the day, and the views of prevailing authorities; and instead of accommodating it to the peculiarities of the case and to the effects produced by it, an indiscriminating mode of administering it has been too generally adopted. At different periods of medical history, and by different physicians, very opposite kinds of food have been recommended. Some have advised a milk diet, while others have recommended a meat and vegetable food only; many a combination of both; some have allowed a large proportion of animal food; and even not a few have permitted the use of fat meats, and a rich, full, and nutritious diet. The praises of certain kinds of diet have often been accompanied by denunciations of all others. Thus the inexperienced, and those who treat a disease according to its name, and not according to the successive pathological conditions it presents, are bewildered, and an important part of the treatment is adopted and applied not more rationally than if it were drawn by lot, or were the turn-up of the die. Now, each of those kinds of diet, modified and added to, according to circumstances, is appropriate and beneficial when appropriately employed, and when aided by a regimen judiciously prescribed. The diet in this stage should always have strict reference to the regimen, which the situation and circumstances of the patient permit, and especially to the locality, temperature, and air in which he resides; and both diet and regimen ought to be directed according to his temperament and diathesis, to the states of vital power and vascular action, as indicated by the pulse and by the febrile symptoms, and to the indications of existing local lesions.

300. When the disease is not ushered in by hemoptysis, or by indications of active concretions, and especially when it is traced to depressing or exhausting causes, then a nutritious diet, animal food in moderate proportion, the white kinds of fish, boiled, with a squeeze of lemon, with little or no other kind of sauce, and shell-fish, especially when they are boiled in the liquor of the fish, the fresh oil of the cod, torsk, ling, haddock, and coal-fish, and the fresh oil of their livers, may be very beneficially used as sauce for these kinds of fish; or the oil may be taken in a more strictly medicinal form soon after a meal. In these and in similar states of the disease even richer and more nutritious kinds of food than those may be tried, and the effects carefully observed. I have often advised a frequent use of fat venison, in some cases, and the fat of lambs or of mutton boiled in milk in others, with much benefit. In cases where this stage is chronic, or where the congestive or no accelerative effect of the pulse, by despondency, by a poor state of the blood, and by absence of sub-inflammatory or congestive symptoms, a dry and nutritious diet, or a more full and restorative diet; animal food, consisting of mutton, game, &c., and even wine or malt liquors in small treatment, may be allowed, if exercise in the open air, especially horse exercise, short of fatigue, be regularly taken.

301. For persons of a fuller habit of body, or more languid or languid temperament than those just referred to, and especially when oppression, or constipation, or pain at the chest, or a dry, hard cough is complained of, the diet should consist chiefly of milk and of farinaceous and vegetable substances, ripe fruits, &c., and the antiphlogistic regimen should be adopted in every respect; but it should not be carried too far, especially in the scrophulous diathesis. In these cases, local depletions, issues, and other derivatives, as will hereafter mentioned, should be employed according to the state of the pulse and other peculiarities of the case. For these, buttermilk, whey, and skimmed milk are excellent beverages and aids to diet. After the more inflammatory and congestive symptoms are relieved, when issues or secretions have commenced to discharge, then a more liberal and nutritious diet may be allowed, and the cooling, antiphlogistic, and febrifuge medicines hitherto prescribed may be changed for those which are more restorative, and more calculated to support vital power and to promote a healthy assimilation. In these circumstances the fish diet, as advised above (§ 300.), may be first employed, and the more nutritious articles of food be afterwards given with caution.

302. b. In this stage, change of air, voyaging, more particularly in latitudes from 30° to 50°, or from 10° or 15° to 30° in winter, in vessels possessing comfortable accommodations; travelling in temperate and warm climates, with due regard to the temperature and climate and to season; residence in a warm and dry air, the elevation above the surface of the sea, and the degree of atmospheric dryness being such as the patient finds to be most beneficial; regular exercise in the open air, preferably on horseback, and short of much fatigue; are severally of manifest advantage. Exercise on horseback is, however, rarely of benefit to females, and is generally too
TUBERCULAR CONSUMPTION.—TREATMENT OF FIRST STAGE. 1149

exciting, and consequently exhausting to them; walking or driving in an open carriage being more beneficial. In all cases, extremes of temperature, and sudden changes or vicissitudes of temperature must be avoided, even by those who are able to take active exercise, as well as by those who are much less able.

303. Travelling, at proper seasons and hours of the day, is generally beneficial, especially when the patient is able to travel on horseback. Travelling on land by other conveyances is less serviceable; although an open carriage, when the weather will admit, is little inferior to riding, especially in the cases of females. But, when a close carriage is used, the patient should sit with his back to the horses; and when he travels by railway, this seat should always be taken, a sufficient ventilation of the carriage being always preserved.

304. Tepid and cold-sponging and washing the surface of the body, or the surface of the chest merely, with variously medicated lotions, have been advised in this stage; but, excepting with those already mentioned, or with the lotions, liniments, and embrocations about to be noticed, this practice is seldom of much service when this period is far advanced, unless exercise can be regularly taken in the open air, and flannel be constantly worn nearest the skin. It is, however, beneficial when employed as a preventive measure for the pulmonary consumption, and for those other on the sea-coast, possess equal advantages as to dryness of the air; as to annual, monthly, and daily ranges of temperature; and as to vicissitudes of weather, and facilities for outdoor exercise, that the inland situation should be preferred.

305. a. A winter residence is of the greatest importance in this stage to patients in cold or temperate climates, for that residence should be selected which will admit of regular and daily exercise in the open air. But this is not the only consideration by which we ought to be guided. Elevation above the surface of the sea, a situation near the level of or close to the ocean, or removed at a distance from it, and frequent or prolonged voyaging on it, are several topics which require to be duly considered. As to the last of these—voyaging—very well-founded expectations of success from it may be formed, if it be commenced in this stage, or before the second became far advanced, more especially in cases which have been attended by hemoptysis at their commencement or early course, and if it be continued for a sufficiently long period. Voyaging in the Mediterranean or in the Atlantic between the degrees of latitude named above (§ 302.), and preferably in the Pacific Ocean, especially when prolonged, either in naval cruisers, or by repeated voyages, so as to avoid the winter and spring of this and other countries unfavourable to consumptive patients, deserves to be more frequently recommended than it has hitherto been. Now that the passage across the isthmus of Panama is easy, voyages thence, in various directions in the Pacific Ocean, may be made, and a return to this country effected in May or June.

306. Elevation above the surface of the sea, especially when warm, and when dryness of air is attained by elevation, is generally beneficial. Even in temperate climates, where elevation is conjoined with dryness, the diminished temperature which results is not so injurious as generally believed. The cold of Canada is by no means injurious to the consumptive, owing to the dryness of the air being great in proportion to the lowness of temperature. If such a residence admits of regular exercise in the open air, it may be salutary, although a warmer air, and an exemption from sudden atmospheric vicissitudes, may be preferred.

307. The only question connected with residence that remains to be considered is, whether preference should be given to a sea-coast or to an inland locality. This is a difficult question to answer; and judging from the indisputable advantages derivable from sea-voyaging, and the very frequent recommendations of places on the sea-coast by modern physicians as winter residences for the consumptive, it may be inferred that these places are actually the most healthy. But this inference is neither logical, nor practically correct as respects pathological cases. The benefit derived from voyaging depends chiefly upon uniformity of temperature and the motions of the vessel, aided by the influence of a pure sea-air, on the digestive and assimilating functions. Residences on the sea-coast furnish only two of these elements of benefit, in an imperfect manner, but they are altogether deprived of the third and that which appears to be the most important. We must therefore refer to the results of observation for a decision; and, as far as my experience enables me, I may state, where two localities, one inland and the other on a tubercular coast, possess equal advantages as to dryness of the air; as to annual, monthly, and daily ranges of temperature; and as to vicissitudes of weather, and facilities for outdoor exercise, that the inland situation should be preferred.

308. Whatever be the locality adopted for the consumptive, or however the patient may be limited in his choice, exercise should not be neglected, in air and sunshine, whilst he is able to enjoy it; and the temperature of his sleeping apartment should not fall below 68°, or rise above 76°. The advantages derived from stoves, when properly regulated, are shown by their preservation of the warmth of apartments at all hours of the night; but a due ventilation ought always to be preserved where they are the only means of keeping the temperature at a proper elevation. Having insisted upon regulation of diet and regimen appropriately to the pathological states of the case in this stage, and upon the advantages of change of air, of travelling, voyaging, and of suitable residence during the winter and spring months, the means which are more strictly medicinal are next to be considered.

309. B. The strictly medical treatment of the first stage of phthisis must depend entirely upon the firmness, temperament, and habit of body of the patient, and upon the states of vascular action, of local lesion, and of vital power. The predisposing and determining causes should also be kept in view; for these should influence or even almost change our indications and means of cure.—a. In cases where vascular action is excited, or the pulmonary circulation is oppressed or congested, or where pain is felt in the thorax, hemoptysis occurs without being very copious, neither anaemia nor vital exhaustion being remarkable, bleeding ought not to be either neglected or delayed. The only consideration is, in what manner it may be most advantageously resorted to. Venesection, unless the patient be robust...
or plethoric, is rarely required. Scarification and cupping are most frequently to be preferred, as the circumstances are few in which this operation may not be efficiently performed, and a due regard to economy, whilst operations should be performed in a very short period, the operation itself generally proving a salutary derivative. When the quantity of blood to be taken is small, and in certain complications, the application of leeches may be preferred.

310. The quantity of blood abstracted at one time should be small, or at most not great. In the majority of cases it may vary from four to twelve ounces; this last amount being allowed only where the habit of body and circumstances of the case appear the most to acquit depletion. Time should be allowed to observe the effects of the first bleeding; and after a due interval, if the symptoms still continue, or upon the return of the indications for having recourse to it, the operation may be repeated. The amount and the repetition of the depletions should be determined only by the peculiarities of the case and the judgment of the physician. It will often be observed that even when bleeding appears to be required, it is but ill endured, although the quantity withdrawn has been small. When this stage is developed by the suppression of an accustomed discharge, as of the catamenia, or of hemorrhoids, then the necessity of the operation is obvious, and that method of performing it which is most likely to re-establish the interrupted discharge should be adopted. Leeches may be applied around the anus when the hemorrhoidal discharge has been suppressed; and beneath the groins when the catamenia are interrupted, difficult, or scanty; and, for both causes of aggrava-
tion, calomel, the preparations of aloes, and warm fomentations or the hip-bath, may be pre-
scribed. The older writers advised bleeding from the feet when immersed in hot water, in cases of cataminal obstruction, and this mode may be adopted by those who prefer it. I have sometimes prescribed it, and seen it employed, with benefit.

311. Vascular depletion has been advised in the first stage of phthisis by some authors and reproved by others. I have now stated many of the symptoms of a rheumatic fever which require it; but there are others, more especially certain complications hereafter to be noticed, which also are benefited by it. But cases are common for which, even at an early period, bleeding cannot be ventured on with safety; or, if employed at all, it can be pre-
scribed only to a small amount, and in the im-
mediate vicinity of parts which appear to re-
quire it. The numerous cases of causes caused by the depressing and exhausting causes mentioned above (§ 192.), by want, by misery, by delib-
erating discharges, by confinement and isolation in factories, close apartments, &c., and by seden-
tary and ill-rewarded occupations,—those cases which present anæmia, cachexia, disc coloured, and debilitated appearances, or in which the pulse is either slow and beneath the healthy condition, or the quantity of blood withdrawn in a very short period seems to be thin and poor in red globules,—are severely injured even by the smallest local depletions, unless they be prescribed for the re-
moval of the pains occasioned by pleuritic com-
plications, for which the additional and often more successful means hereafter to be noticed should be employed.

312. The indications for and against vascular depletion in an early stage of phthisis are, how-
ever, not always to be depended upon. Whilst many are manifest, others may be doubtful. Much, therefore, should be left to the enlightened experience, and the acumen of the physician, in the interpretation of these indications and the discovery of others. The season, climate, peculiarities of race, modes of living, and pre-
vailing constitution and character of disease, the prevalence of a phthisic or asthenic constitutional condition, or morbid action, are severally weighed in his mind before bleeding in any way, its amount and its repetitions are decided upon, and before other important means are prescribed. The prevailing constitution of disease, so much insisted upon by SHENHAN, differs most remarkably in different periods of time. The asthenic constitution, so general in the first quarter of the present century, was changed to the asthenic in the second quarter, and this latter still appears to continue. The vital energies of the residents in large cities and manufacturing towns in both these, are weaker than those possessed by the inhabitants of rural districts and elevated localities; and these differences, with others manifested by indi-
vidual cases, require due consideration when devising our indications and means of cure.

313. The necessity of having recourse to vas-
cular depletions, especially to local depletions, when congestion, sub-inflammatory action, pain, the state of respiration or of cough, or other symptoms, require them, does not necessarily prevent the exhibition of nutriment and even of restorative means, more particularly when vital power appears depressed and vascular action is not much increased. Indeed, in large cities and manufacturing towns, these latter medicines, or even more tonic remedies are often required, although local depletions are equally necessary for the local lessons. For these milder tonics, conjoined with sedatives and narcotics, as the infusions of cheryta or calumba, with hydro-
cyanic acid, or comium, or bocoaum, or the tincture camphor comp., may be first pre-
scribed, and be followed, according to the effects observed by infusions or droppings of the more tonic kind. When, with debility, a cachectic or an anæmic appearance is present, the prepara-
tion of iron may be given, commencing with the mildest. I have generally preferred the mistura ferri composita, with the extract or tincture of comium, or the powder or extract of liquoric; and, if the bowels be sluggish, and the catama-
nia be deficient, with a sufficient quantity of the decoctum aloes composum, or tinctura aloes.

314. The effects of chalybeates of every kind require to be closely observed in this as in every other stage and state of the disease. This class of medicines are contra-indicated where any inflam-
matory complication exists, or where a tendency to hæmoptysis is observed, unless hæmorrhage is of a small, acute kind; and, when the blood is inferred to be thin and poor in red globules,—are severely injured even by the smallest local depletions, unless they be prescribed for the re-
moval of the pains occasioned by pleuritic com-
plications, for which the additional and often more successful means hereafter to be noticed should be employed.
TUBERCULAR CONSUMPTION.—TREATMENT OF FIRST STAGE.

315. When the above medicines are either not indicated or prove inefficacious, the infusions of cimomona, prepared either with cold or with warm distilled water, may be prescribed with hydrocyanic acid, or with any of the preparations of sodium or hyoscyamus; and it may be taken in milk in which a little of the bicarbonate of potash, or of soda has been dissolved. When febrile symptoms harass the patient, the liquor ammoniae acetatis may be given with the infusion of cinchona, and the spirit of nitric ether and hydrocyanic acid added to them. In some instances the liquor ammoniae acetatis may be prescribed with an excess of acetic acid, especially where haemoptysis occurs; and in others, particularly where sinking or exhaustion is present, with an excess of the carbonate of ammonia, other substances which the symptoms will suggest being also added.

316. In this early period of phthisis the functions of digestion—of both stomach and liver, are often more or less impaired; and it is often beneficial to them, as well as to the state of circulation in the lungs, to commence the treatment with an emetic. The older writers recommended this practice, and experience has shown that, when the emetic has been judiciously selected, and the treatment otherwise appropriate, benefit has been produced by it. The Italian physicians, and after them Liebknecht and his pupils, prescribed tartarised antimony as an emetic in this disease, having, as they believed, derived great advantage from it in the more strictly inflammatory diseases of the lungs; and not only did they employ it as an emetic, but as a cura-stimulant, and in doses which were seldom efficacious in reducing the febrile symptoms, but which rarely failed in reducing the vital powers of the patient. I frequently saw the effects of this substance whilst it was in vogue, and sometimes prescribed it; but I considered it of inferior utility to ipecacuanha and to sulphate of zinc as an emetic in phthisis, their operation being facilitated and increased by a draught of a weak infusion, tepid, of camomile flowers. Afterwards demulcents or emollients, or stomachics, with the addition of a little hydrocyanic acid, if the retching or vomiting be more than we desire, may be prescribed, and subsequently the other internal remedies which the features of the case will suggest.

317. The effect of the emetic early in this stage, and the repetition of it when the functions of digestion are disturbed, will generally be beneficial, as shown by the appetite and the state of the evacuations, especially when followed by the medicines just mentioned, or by small doses of the nitro-muriatic acids taken in the tonic infusions already noticed, or in others which the state of the case appears to require. If the bowels become irritable, the tinctura camphora comp., or the pilula saponis composita, will correct the disorder; the former being given in the misted creta, or any other suitable vehicle or form of combination, the latter with small doses of ipecacuanha, and of an aromatic powder. If the biliary secretion be deficient, as not infrequently observed in this period, although the bowels are relaxed, Plummer’s pill or blue pill may be cautiously given, with soap and extract of urinals, instead of the nitro-muriatic acids; or these latter may be prescribed instead of the mercureal, an occasional dose of which should only be taken. In this stage of the disease the bowels are more frequently confined than much relaxed, and the intestinal secretions and excretions are very often more or less disordered. It thus becomes an important object to invigorate these subjoined actions, and to regulate the function of defaecation. The medicines just named will often aid in attaining this end; but they require to be either conjoined with others, or followed by suitable laxatives or aperients, conjoined with vegetable tonics, stomachics, &c. I have also observed great benefit result from the following, when appropriately administered or modified:—

318. These medicines are most suitable in cases devoid of any inflammatory complication, which, as occurring either in this or in subsequent stages, will be more particularly considered in the sequel. The objection of not being applicable to these and other complications cannot, however, be urged against equal proportions of magnesia and sulphur as an aperient in this stage, especially when rendered more agreeable by the addition of liquorice powder and a little ginger. Where this aperient proves too depressing, or where vital power and vascular action and assimilation are much impaired, a little powdered cascara will be added to the former, the whole being taken in some warm water.

319. b. External Medication is a very important part of the treatment of phthisis; and, as will be seen from the historical sketch given above (§ 242. et seq.), it has been considered such from a very early period of medical history. Probably external derivation by means of moxas was as early resorted to in eastern countries for this and other diseases, as by issues and setons among the Greeks and Romans; but there can be no doubt of the benefit to be derived from these and similar means in aid of judicious internal treatment and regimen. As it was in respect of internal, so it has been as regards external means, different kinds and various modes of prescribing them having been advised in successive ages, and those which had fallen into disuse having been revived from time to time, again to be neglected or forgotten. The moxas employed in far eastern countries from time immemorial came into vogue in Europe after the former were visited by voyagers and travellers from the latter; but failed in superseding issues and setons, which have always held their place, and deservedly.
the treatment of this disease, especially with the judicious and experienced. Early in the present century moras came again into use in some parts of the continent of Europe, and postula-
tion by means of tartarised antimonial ointment or of croton oil in this country; the latter means having so entirely superseded issues and setons as to have caused the complete disuse of them. I have seen much of these modes of derivation, and have had considerable experience of their effects, both in phthisis and in other diseases. Moras are of more or less use according to the amount of discharge which may be procured subsequently to the mucedonessence; but their operation is uncertain. Both the tartarised antimonial ointment and the croton oil liniment produce ex-
ternal irritation, but little discharge, their influence on the disease being seldom beneficial, while they distress the patient and even augment the constitu-
tional disturbance in some cases.

320. Issues, made sufficiently large, have proved most beneficial in my practice. I have always prescribed them when I have seen the patient in the first, or even in the second stage, and several persons are now alive who had recourse to them from twenty to thirty years ago, as I advised them. I have generally recommended them to be made near the margin of the rib, when the patient is not much emaciated; or in any other situation which may be preferred. The chief objection to them is the preliminary measure of destroying the integuments for the lodgment of the peas. Where setons appear preferable, as respects the state of the patient, or the situation in which they may be inserted, so as least to inconvenience him, care should be taken, in respect of them as well as of issues, that they should be sufficiently large to be effective, and that a free purulent discharge be uniformly procured from them. When both issues and setons are objected to, especially the forma-
tion of an issue in the usual way, then the inner bark of the mezeceon, previously moistened, may be placed on a part of the surface of the extent of a crown-piece, and confined there by means of a larger piece of adhesive plaster spread on paper or leather. Thus the lead is kept open and the lungs and bronchi are kept open, and the patient may be kept alive. This latter plan, however, is not preferable to a blistered place of this extent kept open and discharging by the usual means; but neither the one nor the other is so effective as an issue or a seton. The benefit derived from the use of the substances, also, generally prescribed for inhalation, has been used in so concentrated a form, or are so acid or stimulating, as often to increase the irritation in the bronchi, or the morbid action in the substance of the lungs, and in the seats of varices or of cavities. It is also very questionable whether or no the inhalation of vapours, whether watery, emollient or anodyne, or narcotic, or possessed of all these properties, is actually beneficial in phthisis, more especially at an early period of the malady. The inhalation of these may be useful as palliatives at an ad-
vanced stage, especially when an irritable cough, a sense of constriction in the chest, difficult ex-
pectoration, &c., are much complained of; but, in other circumstances and stages of the disease, they only tend to over-water the lung or impede the functions of the lungs, by interrupting the progressive metamorphosis and oxygenation of the globules of the blood, and by favouring congestion or a partial collapse of the organ. The modes of inhalation, or of having recourse to the respiration of the atmosphere, or of inflating the lungs calculated to prove beneficial in this disease, will be described in the sequel.
TUBERCULAR CONSUMPTION—TREATMENT OF THE SECOND STAGE. 1153

325. C. Treatment of the second stage of the common form of phthisis.—At the commencement of this period, or when the symptoms, especially the appearances of the expectoration, and the character of the febrile action, indicate the recent supervision of this stage on the first, then it will become a question how far the means which have been adopted will be continued, may be con-
    tinued, and in what they may be modified or changed, or what additions may be made to them.
    In this the physician will be guided by the peculiarities of each case; but, in the circumstances of most, the same principles and means as have been discussed should be continued, modified so as to meet prominent symptoms, and commencing or fully developed complications, or intercurrent affections. The softening of the tubercles in this stage is generally attended by an increase of cough and expectoration, of the hectic symptoms, and of the morning perspirations, with occasional attacks of rheumatism of the bones of the extremities. One or more of these usually become more prominent as the disease advances; or other phenomena are superadded, requiring the treatment to be directed more especially to them.

326. a. The cough generally suggests palliative, in some cases, a purgative medicine with a view to reduce the states of the patient demands. Thus hydrocyanic acid, or henbane, or hemlock, or the compound tincture of camphor, may be added to mixtures containing the liquor ammonii acetatis, and any demulcent which may appear most appropriate to the nervous and vascular conditions of the case; or they may be con-
    joined with bitter or tonic infusions or decoctions, when the states of the pulse, of the fever, and of the vital powers, require them; these latter are often rendered more beneficial by the addition of the solution of the acetate of ammonium, and of the sweet spirits of nitre. Where there is much pallor of the surface, the pulse being either weak or but little accelerated, any of the anodynes above mentioned may be added to the mixtura ferri composita, and the effects upon the cough and upon the hectic and other symptoms carefully observed.

327. b. The perspirations during the night or early part of the morning are always productive of great exhaustion, and are the most difficult to restrain or prevent. They have been very differently treated by both ancient and modern physi-
    cians, but most frequently by mineral acids, and by various refrigerants, astringents, and tonics, as shown in the historical sketch given above (§§ 241. et seq.). Either of these may be prescribed in combinations suited to the case, with emollients, stomachics, or tonics, and may be made the vehicle, on the surface of which the recent cod.
    line oil may be taken shortly after a meal, twice or thrice daily, and in sufficient quantity; this being the substance most deserving of reliance for moderating this distressing symptom. Some of the medicines advised with this object have often disordered the bowels, or induced an attack of diarrhoea, and even augmented the suffering of the patient without producing the effects desired. The perspirations and their consequent exhaustion; but these results rarely follow from the use of this oil. The mixtura ferri composita is sometimes of service in alleviating the severity of the hectic and the excessive perspirations, especially when there is no inflammatory complication present, and when it neither produces headache nor renders the cough harder or more severe. Dr. Watson has found the tinctura ferri muriatis successful in allaying the perspirations after other means had failed. The dose be prescribed of this medicine is twenty minims thrice daily. I have likewise given this preparation, with advantage, in the in-
    fusion of calumba, with an addition of twice the usual quantity of the acid, and have sometimes made this combination the vehicle on the surface of which the cod-liver oil was taken.

328. c. When diarrhoea occurs it is often induced by some purgative medicine, or by errors in diet, or by means employed to moderate the perspirations. The cause of it should be ascertained, and the medicines to restrain it be suggested or selected accordingly. It is, however, frequently independent of either of these causes, and the result of indigestion—of the acidity and the accumu-
    lation of sordes in the prana via consequent upon the imperfect performance of the functions of primary assimilation. In either of these circumstances antacids and absorbents, conjoined with mucilages, anodynes, or narcotics, or with mild tonics, will prove of service; as the creta-
    ceous mixture with the compound tincture of camphor, or the tincture of poppy, &c., with the tincture of eau de chou, or with other vegetable astringents, if they be required. But the bowels should not be confined by these or other medi-
    cines; and when there is any risk of such an occurrence magnesia may be given with sulphur or rhubarb, or with cascara; or the compound decoction of aloes may be prescribed with the tincture or with other suitable medicines.

329. d. In this stage of the disease emetics and bleeding are seldom beneficial, unless the states of the digestive and respiratory functions require a recourse to the former, and the occurrence of pain or the appearance of an inflammatory or congestive complication demand the latter. Ippecacuanha is in most instances the best emetic, and local bleeding the most beneficial, especially when the embrocation prescribed above (§ 321.) is afterwards applied and daily persisted in. Although it may be necessary to have recourse to these means, others of a restorative or even tonic kind—both medicinal and regimental—may be equally required; often, however, in different cases, but not infrequently in the same case, and sometimes even soon after the more antiphlogistic measures have been employed. Generally, when local de-
    plications are required, febrifuge medicines, chiefly such as the solution of the acetate of ammonium, camphor mixture, &c., are the most appropriate; but they may be afterwards conjoined with others of a more tonic nature, such as the infusion of hop or the infusion or decoction of cinchona, and to these anodynes may be added; the selection of which should depend upon the features of the case. Hydrocyanic acid, monkshood, hemlock, henbane, meadow-saffron, and digitalis, have been individu-
    ally employed in combination with these or other medicines; but they require caution in their use, and careful observation to diminish the effects. Tinctura pulmonalis or muriate is most appropriate in the more inflam-
    matory tendencies of this and the preceding stage, but it especially demands a most cautious obser-
    vation of its effects; a remark not less applicable to colchicum and digitalis, which are suited to the same states of the disease as those for which muri-
    ata is prescribed.
nite may be given; these being useful chiefly as antiphlogistic means, either in aid of vascular depletion, or when the condition of the blood and of vital power contra-indicate a recourse to depletion; although the local morbid action requires to be restrained or even lowered.

330. The remarks offered above respecting issues, setons, and other derivatives (§§ 319—323), apply to this, as well as to the first stage. Instances are rare in which either the one or the other should not be resorted to. The great difficulty often is, owing to the emaciation of the patient, in which situation they may be placed, so as to produce the least amount of discomfort. When emaciation is not very remarkable, then the margins of the ribs may be selected; but in different circumstances an issue of good size may be formed over the pectoral muscle, or between the shoulder-blades. When this stage in females is characterized for this mode of administration, and of the catamenia, the issue may be made near the groin, in the anterior aspect of the thigh. When setons are preferred, the arm, near the axilla, may be selected. If neither of these, nor moxas be adopted, blistera, kept open as long as possible and effective, and a surgically necessary. The embrocations advised above (§ 321.), ought not to be overlooked, inasmuch as, in the more urgent cases, they may be applied whilst the foregoing means are also in operation, and as they are sources both of derivation and of inhalation. When the above produce a sufficient discharge, then Griffeth’s myrth mixture, or other chalybeates or tonics, may be prescribed, with anodynes, narcotics, &c.; and their effects upon the cough, the pulse, and the hectic should be carefully observed. If these symptoms become aggravated by them, they ought to be relinquished, and the salines, especially the solution of acetate of ammonia, or of citrate of potash, with hydrocyanic acid, conium, &c., as noticed above (§ 329.), may be substituted. If these effects do not result, then the more generous regimen recommended for the first stage (§§ 314. et seq.) is equally, if not even more, required for this.

331. f. Inhalation of dilute medicated vapours and fumes may be tried in this stage, as well as in the first. The opinion I have formed of them, and stated with reference to that period (§ 324.), is not materially different as regards this. Cases may occur in which they will be more serviceable in the second than in the first stage, and still more so in the third than in either of the foregoing: but the amount of benefit, or the want of it, will entirely depend upon the substances selected; for any mode of administration, and in the way of effecting this intention (see § 412.). But mild or weak fumigations of the patient’s apartment are generally much more beneficial than inhalations, which often irritate and increase the local lesions (§ 413.).

332. g. In females the stage of the catamenia, as respects both the intervals and the duration and quantity of the discharge, is of the greatest importance, especially in the first and second stages of the malady. Excessive discharge, whether as to frequency of recurrence, the duration of its continuance, or the quantity, not infrequently predisposes to, or more directly occasions, phthisia; and the same disorders of this function, if allowed to proceed, will also aggravate or hasten the progress of this malady, if they occur in either the first or second stages. The rapid or sudden disappearance of this discharge, on the other hand, is even more certainly and rapidly injurious, in whatever stage this may take place. A difficult or scanty catamenial discharge requires attention, although it is not so dangerous as either of the former states, especially the latter. Excessive states of the catamenia should be moderated with caution and by such means as are not likely to be followed by suppression. The dejection or infusion of cinchona with either of the mineral acids, or the sulphate of quinine in the compound infusion of rose, and tincture of orange-peel may be prescribed, or the sulphate of quinine may be mixed in some water and taken without any addition. If amenorrhoea have been produced by this discharge, the tincture of the sequinolized dimmitans of the catamenia, the issue may be made near the groin, in the anterior aspect of the thigh. When setons are preferred, the arm, near the axilla, may be selected. If neither of these, nor moxas be adopted, blistera, kept open as long as possible and effective, and a surgically necessary. The embrocations advised above (§ 321.), ought not to be overlooked, inasmuch as, in the more urgent cases, they may be applied whilst the foregoing means are also in operation, and as they are sources both of derivation and of inhalation. When the above produce a sufficient discharge, then Griffeth’s myrth mixture, or other chalybeates or tonics, may be prescribed, with anodynes, narcotics, &c.; and their effects upon the cough, the pulse, and the hectic should be carefully observed. If these symptoms become aggravated by them, they ought to be relinquished, and the salines, especially the solution of acetate of ammonia, or of citrate of potash, with hydrocyanic acid, conium, &c., as noticed above (§ 329.), may be substituted. If these effects do not result, then the more generous regimen recommended for the first stage (§§ 314. et seq.) is equally, if not even more, required for this.

333. Scanty or difficult menstruation requires means appropriate to the peculiarities of the case; for either of these states may be attended, in one patient, with an unsymmetrical or chlorotic appearance, and, in another, with little or no apparent deficiency or poorness of blood. In the former case, the compound mixture of iron, with as much of the compound decoction or the tincture of aloes as will act moderately on the bowels, or prevent constipation, with a little of the extract or tincture of conium, will generally be of service. In other cases, where there is no deficiency of blood, a few leeches may be applied below the groins shortly before the expected period of the catamenia; and the hip-bath and pediluvia, at a sufficiently warm temperature and with the addition of salt or mustard, resorted to.

334. In cases attended by suppression of this discharge, strenuous efforts should be made to restore them. The hip-bath, pediluvia, &c., rendered stimulating by bay salt and mustard, leeches applied around the anus, or beneath the groins, the preparations mentioned above (§§ 333.), walking exercise, or riding on horseback or in a carriage, and the several emmenagogues advised for suppression of the catamenia (see Menstruation, §§ 64—95. et seq.), should be prescribed in combinations or forms suited to the state and stage of the pulmonary disease.

335. In this stage various complications appear, either as temporary or intercurrent affections, or as morbid associations, which continue to the termination of the malady. These will be noticed in the sequel; but there is one which is rarely absent, and which renders the treatment difficult, namely, the bronchitic affection. This in many cases becomes the prominent disorder, and requires the treatment to be more especially directed to it; the most generally ser-
TUBERCULAR CONSUMPTION — TREATMENT OF THE THIRD STAGE. 1157

viceable means being, according to the accompanying fever and the state of the patient, the solution of the acetate of ammonia with the spirit of nitrous ether, dilute hydrocyanic acid and camphor mixture; or in somewhat different states, with carbonate of ammonia, composed tincture of camphor, or benzoate or conium. If there be a lasting cough, with copious expectoration, this may be added; and in most cases the terebinthinate emulsion should be applied to the chest.

336. h. The diet and regimen in this stage may, in a very large proportion, if not in the majority of cases, be altogether the same as I have advised for the prevention and for the treatment of the first stage of the disease (§§ 292—308.). In many cases a fish diet will agree well in this stage; the white kinds of fish, always boiled, but never fried, a squeeze of lemon, with little butter, but preferably with the liver of fish, being the chief or only sauce. The fish and their livers, which are most beneficially used as articles of diet, are the Gadus breamius, or torsk; the Gadus morhua, or cod; the Gadus melus, or ling; the Gadus anguifrons, or haddock; the Gadus merlangus; the Gadus callarias; the Gadus carbonarius, or coalfish; the Gadus theracis, &c. The recently livers of all these species of the genus Gadus, boiled in such a manner as to preserve their oil, may be used either as sauce to the fish, or may be ate with it, or the oil may be taken after the meal, in the usual medicinal way. They are beneficial both as articles of diet and as medicine. When quite recent they have no fishy or unpleasant flavour, and are easily digested, — the more easily the more oil they contain.

337. As to other articles of diet, regimen, change of air, exercise, travelling, voyaging, and choice of residence, the remarks which I have made above (§§ 292—308.), and in the sequel (§§ 420, 421.), and in the article CLIMATE (§§ 42. et seq.) are applicable to this stage, according as the strength of the patient and the prominent symptoms will admit of their adoption; and as the presence or absence of any of the more important complications will suggest.

338. D. The treatment of the third stage of the common form of phthisis (§§ 38. et seq.), is frequently but little different from that already advised. The state of the patient may not, in some instances, be materially different from that characterising the second stage, although cavities — one or more — have already formed in one or even both lungs. The patient may not be materially worse in respect either of strength or degree of emaciation, or of cough and respiration, especially if the more aggravated symptoms and complications have not as yet been experienced. More commonly, however, he is much worse as regards all these: and colliquative perspirations, attacks of diarrhoea, severe paroxysms of cough and of oppressed breathing, and pains in various parts of the chest or its vicinity from inflammatory congestion of portions of the lungs or from the extension of the morbid action to the pleura, are more or less experienced, and are generally relieved with greater difficulty than in the preceding stages. The treatment depends chiefly upon the complication, or rather complications, which characterise this stage.

339. a. In all cases there is more or less bronchitis, chiefly, however, of the bronchi communicating with the softened tubercles and cavities; but there may be in addition inflammatory, or sub-inflammatory action in the surrounding portions of lungs, or even also in parts of the pleura in the vicinity. These may require, or at least suggest, a treatment which neither the strength nor vascular condition of the patient may well bear, especially when carried so far as to subdue the super-induced local mischief. But to leave these matters to their natural courses, when clearly manifested by symptoms, may be more injurious than the effects of judicious means proscribed for their removal; and, as far as my experience enables me to decide, the employment of such means is the safest alternative. For these states of this stage, therefore, local depletions, by leeches or by cupping, are required according to the condition of the patient and symptoms of the case, the quantity of blood taken at first being small. When the indications for having recourse to this measure are doubtful, dry-cupping, afterwards blisters, the terebinthinate emulsions already advised (§ 321.), and the sebumgine medicines recommended above, are most appropriate. Of this class of medicines, the solution of acetate of ammonia, in forms and combinations already noticed (§ 315.), is the most generally of service.

340. h. In this stage, especially in its later course, the colliquative perspirations and diarrhoea exhaust the patient and more or less waste the red globules of the blood. Whilst these symptoms should be restrained, the powers of life and the supply of duly assimilated blood-globules must be supported and promoted. The means which fulfill the one indication often also aid the other. This is more particularly demonstrated by the effects of cod-liver oil, and by medicines which improve the digestive and assimilating processes, and correct, counteract, or remove the contaminating matters which are carried into the circulation from the lesions seated in the lungs, whether softened tubercles or ulcerating cavities, and which thereby affect the cutaneous and mucous surfaces and follicles, so as to give rise to these exhausting and distressing symptoms of the malady. Numerous means, beside those already mentioned, have been proposed for these morbid conditions, especially the acetate of lead with pyrogallic acid and laudanum, the sulphate of zinc with sulphuric acid, the sulphate of copper with opium, the substances containing tannin, gallic acid, &c., and catechu, kino, kraneria, hematomylum, nox vomica, &c.; but very few of these, even while they restrain the diarrhoea, diminish the perspirations, or in any other respect alleviate the malady. Indeed, in some cases they aggravate the disease, and only accelerate its progress to a fatal issue by preventing the elimination by those emunctories of the effete, morbid, and contaminating materials conveyed into and circulating in the blood.

341. c. Much more rational and efficient indications for the abatement of the colliquative diarrhoea and perspirations in phthisis would be the improvement of the digestive and assimilating functions by such means, or combinations of means, as would at the same time, by their partial absorption into the circulation, correct, change, or counteract the contaminating matters which are imbibed from the seat of the disease; whether these matters be purulent or tubercular, or the sanious fluid formed in or on the surface of ulcerating parts, and which, wondrously, they are actually present in the blood or are more or less changed.
TUBERCULAR CONSUMPTION—TREATMENT OF LATENT FORM.

in the course of the circulation of the blood. That they actually contaminate more or less this fluid, however small may be the quantity which passes into it, and thereby give rise to the most distressing and dangerous symptoms of phthisis, cannot be doubted, the skin and the bowels being two of the chief channels through which they, and other injurious matters they may form, are eliminated from the circulation; but the selection of the means of fulfilling these indications is much more difficult than devising them, and depends entirely upon the peculiarities of individual cases, as respects especially the progress of the disease and the states of respiration and circulation. The bicornate and the nitrates of potash, prescribed in tonic infusions or decoctions, with aromatic or astringent or narcotic tinctures, according to the state of the case; magnesia and sulphur, with the powder of caraselli or of cinnamon or ginger and liquors powder, or with other substances, as the state of the bowels will suggest; the compound iron mixture, or the aromatic mixture of iron (D. P.); the bitter or tonic infusions, with carbonate or citrate of potash or of soda and amodyces; balsams, the purified or precipitated ox-gall, with commin or with the compound soap pill and ipecacuanha, or with the purified extract of aloes, according to circumstances; and camphor, the terebinthinates, tar or tar water, conjoined with such of the foregoing medicines as the features of the case require, may severally be employed. In some instances where the colliquative state of the bowels and other symptoms indicated a contumined state of the blood, and consequent alteration of the mucous surface and follicles of the bowels, I have prescribed the following pills at night, or night and morning, or with the meals; the bitter vegetable tonics, with alkalis, &c., having been taken in the intervals between meals:

No. 355. B. Phialis Ferric comp.; Phialis Rhei comp.; Extractum Ferris bovini; Picis liquidae, &c., 3 gr.; Mixce et consumatur bene, dem dividitur succus in pilulas XXXI, quorum capitis unus ad tres pro dose.

No. 357. B. Magnesia carbonis; Sulphuris praecipit. &c.; Picis liquidae Confect., aromata in pulv. ex 5 gr. Oeni ami. &c., 5 gr.; Consumatur 1/2ijij, ad 3ijij pro dose.

No. 358. B. Prim. Rex, &c.; Sulphuris praecipit., &c.; Picis liquidae Confect.; aromata in pulv. sext. &c.; Consumatur 1/2ijij, ad 3ijij pro dose.

These doses, and their effects, are to be watched, than by opposite means. The medicines from which most relief may be expected in the delirium occurring in this period, are camphor, ammonia, the solution of the acetate of ammonia, the carbonate of ammonia, the compound spirit of ether, the spirit of nitric ether, the hydro-chloric ether, the preparations of serpentina, of ar oceans, and of sumbol. These may be prescribed individually, or in combinations of two or more, or with the alkaline, saline, and restorative medicines I have mentioned as being useful when the blood is contaminated, the delirium often arising from that condition, as well as from exhausted organic, nervous, or vital influences.

354. v. TREATMENT OF THE LATE ST FORM OF PHTHISIS.—This variety of the disease (§§ 77. et seq.) generally eludes the notice of the friends and the fears of the patient until it has advanced to a state hardly admitting of hope. If, however, the symptoms characterising it should alarm either friends or patient, if depression of spirits, impaired digestion and assimilation, or other indication of disorder lead to the procuring of medical advice and the detection of the malady in its silent and stealthy course, although no prominent or unmistakable sign be present, the treatment which will be found most beneficial is
that which has been already advised for the Prev-
ence and for the threatened appearance of the
malady (§§ 292—298.). It is obvious, however, that the best advised means will have no beneficial effect if the causes which injured the constitution still continue to act. The physician should endeavor to ascertain what these are; and if they be such as may be removed, the necessity of making the attempt should be insisted upon, and the patient be made acquainted with the consequences of the neglect of this advice, especially when the removal of these causes depends upon himself. In most of the cases of this variety the causes are usually depressing and exhausting; and in many, as soon as the nature of the malady is suspected, the digestive and assimilating functions require restoratives, mild tonics, change of air, moderate exercise in the open air, travelling, and pleasurable occupation of the mind; the regi-
mental and medical treatment I have advised above (§§ 299—324.) for the first stage of the usual form of the disease being also necessary. In this latent or silent course of phthisis vascular depletions are not well sustained; and if they be at all attempted, they should be watched. In the great majority of cases of this form, and especially when depressing or exhausting causes have occasioned the malady, medicines of a decidedly restorative or tonic kind, attention to the digestive functions, cod-liver oil, and the other means recommended at the place referred to, should be adopted. These may arrest the disease; but if it should advance, nevertheless, and become unmistakingly developed, the treat-
ment must necessarily be the same as I have advised for the more common form of the malady, modified as above, according to the manifestations of the advanced stages.

346. vi. Primary Acute or Rapid Phthisis.

A. The symptoms of the first variety of this form (§§ 82—84.) have been described by me as intermediate between those of congestive bronchitis on the one hand, and of congestive or nervous states on the other (§ 82), both lungs being more or less affected. The cases which I have observed have been con-
secutive of measles in a scrofulous diathesis, or of delayed, suppressed, or excessive catarrh. In these bleeding seemed injuries, or was of no avail. Emetics, the solution of the acetate of ammonia, with or without sodium, small doses of camphor, the terebinthinate emulsion applied over the chest or between the shoulders, and blisters, were the means which appeared to be of most service. Cod-liver oil was either not re-
tained, or was nauseated and not taken, or failed of producing any benefit. The infusion or deco-
tion of cinchona, with nitrate of potash and bicarbo-
lates of the alkalis, or with the solution of acetate of ammonia and various ethereal prepar-
ations, and small doses of camphor with aconite, &c., were also prescribed in different cases, or in the same cases at different periods of the disease, but with no marked advantage.

347. B. The second variety, or more strictly fe-
brile form of acute phthisis described above (§§ 85, 86.), is often mistaken for low nervous or typhoid fever, which it closely resembles, especially in its advanced progress. In the few cases which have fallen under my observation I prescribed the rem-
edies I have just mentioned (§ 346.); and of these, the last-mentioned, or those consisting of the preparations of cinchona with the sub-
stances stated to have been conjoined with them, the chlorate of potash, camphor, the terebinthinate
emulsions, &c., appeared to be of service only in prolonging the life of the patient for a few days. The nature of these cases precludes any hope of further advantage than this from any treatment whatever.

348. vii. Consecutively Acute Phthisis

(§§ 87.) is merely the supervision of either of the acute varieties of the disease described above (§§ 81—86.) upon the latent form (§§ 77—80.), or the development of this latter form owing to an attack of haemoptysis in its course, or to some determining or aggravating cause or occurrence. Although an attack of haemoptysis often relieves the pulmonary symptoms when they have been unequivocally manifested previously, at least for a time; yet it is sometimes followed by an acute state of the disease, most frequently by the more common form, when it occurs in the course of the latent variety. In the consecutive manifesta-
tion of acute symptoms the treatment should depend upon the extent of the symptoms and upon the associations they present. If haemoptysis take place, the treatment I have advised for it (§§ 353—5.) may be adopted as far as it may be appropriate to the peculiarities of the case. If the local symptoms and signs indicate congestion or inflammatory action in one or both lungs, local vascular depletions, or even a repetition of them, emetic, antiphlogistic, and saline medicines, especi-
ally the solution of the acetate of ammonia, terebinthinate emulsions, blisters, and other means already noticed, will be of service; and if the disease assume the acute or febrile states, the medicines noticed above (§§ 346, 347.) may be pre-
scribed, although with little or no hope of benefit from them. In some instances the malady as-
sumes a less acute or febrile form, the treatment having temporarily mitigated the severity of the symptoms. This is probably owing to the con-
gestive and inflammatory action of the bronchi and substance of the lungs, which had superven-
ioned upon an extensive but latent formation of tubercles in both lungs having been partially subdued by the means employed. In these cases the de-
velopment of the tubercles by the morbid action in the bronchi and substance of the lungs after-
wards prevents this action in these parts to subsist; and thus both these morbid conditions act and react on each other, so as to occasion an acute state of disease. The extension of these lesions in a more or less marked degree through both lungs generally terminate fatally before large cavities, or even any cavities, are formed; whereas, in the common form of the disease, the greatest part of the lungs remains free from change, al-
though other portions are ulcerated, excavated, or otherwise disorganised. In these circumstances the principles of treatment already developed should be adapted to the peculiarities of individual cases.

349. viii. Protracted Phthisis (§§ 89—91.), especially when early recognised or manifested, and judiciously treated, furnishes many chances either of recovery or of prolonged existence. For this variety, particularly when the pulse and respiration are not much increased, there is a variety of re-
gimenic means advised for the prevention & Sec.
disease and for the treatment of the first stage (§§ 292—323.) are generally of great service, more especially change of climate, voyaging, exercise and agreeable occupations in the open air, and in the temper of the patient, the digestive and assimilating functions, aided by digestible and nutritious food; by sulphur, balsams, a farinaceous and milk diet, &c.; by tonics, stomachics, and chalybeates when the disease appears to have proceeded from depressing or other causes; by emetics and other bracing antiphlogistic means, or by small bleedings, issues, setons, terebinthinate emboctions, blisters, &c., according as vascular excitement or congestive or inflammatory complications may occur. In the simpler states of this form, when the pulse is weak or slow, and no congestive or inflammatory complication is present, especially if the blood be deficient or thin, the mistura ferri composita, or the tinctura ferri muriatit, will be given with benefit; and with either of these other medicines may be conjoined, especially cod-liver oil, another, &c. &c.

350. ix. Phthisis in Infants and Children (§§ 92—95.) requires more particularly the hygienic measures I have recommended under the head Scrofula and Tubercles (§§ 148—153.) and in the sections above on the prevention and early treatment of the usual form of phthisis (§§ 292—305.). Asses' milk, a milk and farinaceous diet, moderate exercise in the open air, change of climate, strict attention to the promotion of the digestive and assimilating functions by means of diet, regimen, and suitable medicine, the cod-liver oil in as large quantity as the stomach will bear, and taken in the modes hereafter to be noticed, are the chief means in which confidence can be placed, although others should be added which the circumstances of particular cases will suggest. When the disease advances to the second or third stage in children, then the treatment advised above for these stages, in the usual form of the disease, will, with due reference to the ages and states of the patients, be equally appropriate for them.

351. x. Phthisis in the Dark Races (§§ 96. and note.)—The forms and states of the disease may reasonably be considered as varying with race and climate (§§ 200—222.), and also with the habitual food and clothing, or amount of clothing, of these races (§§ 219—222., 420. 1. and Climate, §§ 42. et seq.). From what I have seen or gathered from writers respecting the disease in these races, I conclude that for them a tonic and restorative treatment, with attention to the digestive organs and to the functions of the skin, is especially and generally required. In other respects the means of cure advised above for the several forms of the disease in the white races are also suited to these forms when they appear in the dark races. In these latter the causes are commonly depressing and exhausting. Confine them to close situations, where the air is rendered impure by frequent respiration or by numbers, remove to colder and more humid climates than those from which they have been taken, veneer excesses, and insufficient food are the most frequent causes of this state of things, and blood purgatives are a common occurrence at the accession or early stage of the disease. For these the more astringent tonics, the preparations of cinchona or of cascarilla, conjoined with laxatives or aperients, or with diaphoretics, according to the states of the bowels and skin; ippecacuanha combined with the balsams and restoratives, chalybeates with starch, and in the tuberculous localizations externally, are most frequently indicated. If febrile action be present, the warm and restorative febrifuges and diaphoretics are required; especially the solution of acetate of ammonia, the carbonate of ammonia, camphor, and the infusion or decoction of emetics and others by internal and external antiphlogistic means, or by small bleedings, issues, setons, terebinthinate emboctions, blisters, &c., according as vascular excitement or congestive or inflammatory complications may occur. In the simpler states of this form, when the pulse is weak or slow, and no congestive or inflammatory complication is present, especially if the blood be deficient or thin, the mistura ferri composita, or the tinctura ferri muriatit, will be given with benefit; and with either of these other medicines may be conjoined, especially cod-liver oil, another, &c. &c.

352. xi. Treatment of Complicated Phthisis.

The Complications which severally appear from the accession to the close of this disease require a few remarks. These complications are not confined to any one form or stage of the malady, but occur in all; although more frequently perhaps in some cases than in others, owing to the constitution and predisposition of the patient, to the exciting and determining causes, and to the exposures and other influences in operation during the progress of the malady. Some of these complications may appear in the character rather of prominent or more urgent symptoms than of actual superinduced or intercurrent affections; but, as phthisis may, and actually often does, run its whole course without the appearance of any of them, or of one only in some cases and of another in others, whilst two or more may occur even in the same case, although not at the same time, they may be more correctly considered as contingent symptomatic affections, complicating, and often rendering the tuberculous or original malady more severe and more rapidly fatal. With a few exceptions, these affections have already been considered with reference to treatment when discussing the successive stages.

353. xii. Hemoptysis is a frequent occurrence in phthisis. The treatment of it should depend upon the state of the pulse, the age and habit of body of the patient, the stage of the disease, and the amount of blood lost. I have, however, so fully treated of hemoptysis under the head Hemoptysis from the Respiratory Organs (§§ 123—141.), that it is quite unnecessary to entertain this subject farther than to remark that hemoptysis is generally the result, at the accession or at an early stage of phthisis, of capillary congestion arising from the obstruction or irritation caused by tubercular deposits, and at an advanced stage either of the same cause or of exudation from an ulcerated cavity, or of discharge from an eroded vessel or vessels. The older writers, observing the relief following a free discharge of blood at an early stage of the disease, advised that the hemorrhage should be allowed to proceed for some time. These races, and would only alarm the patient, and be running the risk of the blood passing into and obstructing or irritating many of the bronchi which had remained free.
from disorder. It is, therefore, safer to assist the hemorrhage by suitable means, such as those which I have detailed under the article Hemorrhage (§§ 123—141.), or by general or local bleeding, or by the internal exhibition of the spirit of terpentnine in doses of twenty or thirty drops every half-hour or hour, and by the turpentine embrocation or epimorph applied over the chest. There are numerous other means which may be employed, and which are mentioned in the article just referred to; but these are most generally of service. The bleeding should be rather repeated than large, and be regulated by the circumstances already stated. Large doses of ipecacuanha, or one or two grains given every quarter or half-hour, are also of great service; but if the bowels be confined, half-an-ounce each of spirits of turpentine and castor-oil may be taken in a suitable vehicle, and the same substances in larger doses administered in gruel as an enema. Dr. CHEYNE advises, especially in cases of haemoptysis with inflammatory symptoms, a quarter, or even an eighth of a grain of tartarised antimony with five to ten grains of nitre every hour. The chief advantage of ipecacuanha and from antimony is produced by the nausea they occasion. Much, also, of the benefit experienced from sea voyages, especially in this form or complication of phthisis, is also produced by the nausea thereby occasioned.

354. When called to these and other forms of hemorrhage I have often found the practitioner assiduously applying cold or ice to the chest. The instantaneous shock or impression of cold sometimes does good; but if this effect does not immediately follow, to persist in these applications, especially in haemoptysis, always does mischief, by increasing or perpetuating congestion of, and vascular determination to, the lungs.

355. When haemoptysis has not sufficiently relieved the congestion or the inflammatory symptoms attending it, then bleeding, general or local, should be repeated, according to the effect on the circumstances at the time or subsequently. When, on the other hand, the quantity of the discharge, the existing symptoms, the stage of the disease, and state of the patient, require an immediate arrest of haemoptysis, without having recourse to vascular depletion, then the other means advised are the most efficient, the spirit of turpentine or ipecacuanha acting more promptly than the acetate of lead or other astringents. The scale cornutum I have also found to act very promptly in haemoptysis, five grains of it being given every five, ten, fifteen, or twenty minutes, until it produces the effect or causes vomiting or much nausea. The repetition of small bleedings, or of other means subsequently, should depend upon the state of the pulse, the existence of pain in any part, or of dyspnoea and the state and stage of the disease; but in most cases the terebinthinate embrocations already advised should be continued to those regions of the chest where most uneasiness is felt.

356. B. Inflammation of portions of the lungs or of the bronchi, or of the trachea or larynx, followed by more or less of the consequences of these, as stated above (§§ 109—112.), often complicated phthisis, and requires means of an antiphlogistic kind in some respects the same as those just advised. It should, however, be recollected that the inflammatory action affecting one or more of these parts, owing to its asthenic or congestive character, to impaired constitutional power, to previous disease, and to the associated morbid conditions, admits not of the same treatment. But the spirit of terpentnine has been found most beneficial in idiopathic or some other states of this action. Vascular depletions, generally local, as in haemoptysis and pleuritic attacks, are required, and sometimes should be repeated. When the state of the case admits of venesection, this should be continued until the bleeding is very small. All astringent applications should be preferred to the application of leeches, to which also cupping ought to be preferred.

357. a. Pain in the chest, independently of haemoptysis, is often relieved by small bleedings, by cupping or leeches, by blisters, and by the continued application of the terebinthinate embrocation. The usual cause of this pain—its connection with partial pleuritis (§ 112.)—should not be overlooked; and the advantage generally following a recourse to mercurial and antimonial preparations in combination, and sometimes also to atropine, demulcent, &c., in the intervals between the exhibition of the former, ought to be kept in view.

358. b. Cough is often a most distressing symptom, especially in the advanced stages of phthisis, and more particularly when it is associated with dyspnoea. In the less urgent states of cough, compound tincture of camphor, or hydrocyanic acid, will often give relief. The preparations of anised have long been highly esteemed for their effects in ameliorating the cough and even the dyspnoea. To the preparations in common use Dr. Watson states that Dr. Fainor preferred an infusion of three dracontia or half an ounce of the bruised seeds of anised in half a pint of distilled water, at a temperature not exceeding 120°, allowing it to stand until it is cold. This may be made an excellent vehicle for the compound tincture of camphor, hydrocyanic acid, or conium, &c. But the severer attacks of cough, in the advanced stages, require more energetic means, especially the preparations of opium or of morphia. These, however, often are followed by unpleasant symptoms, particularly morphia, if they be not conjoined with aromatics and gentle stimulants—with small doses of camphor, of spirits, or oil of caraway, or of lavender, or of anised, &c. Opium may be given in the form of the confection opii, or conjoined with a little of the confection aromatica; or the pilula galbani composita, or the pilula saponis composita, or the pilula styriaca composita may be prescribed with either of the foregoing. I have frequently preferred the following solution of the acetate of morphia, conjoined with aromatics in order to counteract the depressing effects often produced by it.

359. C. Laryngeal and Tracheal Affections are often the most distressing of those which occur in the course of phthisis (§§ 109.110.); and in some of the usual or more pronounced forms of the disease, present more or less of an antiphlogistic character, and the characters noticed above (§§ 160.110.), or of the sub-acute or chronic states described in the article on Diseases of the Lungs.
TUBERCULAR CONSUMPTION — TREATMENT OF THE COMPLICATIONS.

LARYNX AND TRACHEA (§§105. et seq.). Since this article was written, the diseases of these parts have been ably investigated by Dr. Horace Green. He contends that inflammatory affections of the larynx and trachea, which are the origin of the tuberculous affections of the neck, are always seated in the mucous follicles. It is, however, chiefly in the subacute and chronic affections of these parts, that the follicles are either primarily or consequentially implicated, and especially when these affections are complications of phthisis, and are produced either before the primary irritation of the trachea, larynx, epiglottis, and even of the pharynx and fauces, by cough, and by morbid secretions passing through them, or by the existence of tuberculous matter in their follicles or muciparous glands. At first, these sources of irritation and contamination enlarge those follicles, increase their discharge, thicken and somewhat soften the mucous and sub-mucous tissues, and ultimately occasion an ulceration of the mucous follicles, and an atrophy, with increased softening, of the mucous and sub-mucous membranes. That the affection of the muciparous glands, in the advanced stages of the disease, is accompanied not only by the morbid secretions passing over them, but also by the deposit of tuberculous matter in them, is extremely probable. Dr. H. Green insists upon this latter change, although it is denied by several eminent pathologists. In either case, the treatment cannot materially differ. Dr. H. G. found this complication of phthisis most frequent between the ages of 25 and 38 years. He also often observed this affection of the throat and larynx after influenza, eruptive fevers, and more particularly in persons habitually using tobacco.

Dr. Gellerstedt considers the ulcerations so commonly found in the larynx, in phthisis, to be of tubercular origin; while those of the trachea he regards, with Louis, as of an aphthous nature, arising from the constant irritation of the cough and expectoration.

300. The treatment of this complication of phthisis has been by inhalation, insufflation, leucrosis, and the application of the solid nitrate of silver to the tonsils, uvulae, and pharynx. Dr. Laycock remarks, in an able article in the British and Foreign Medical Review (vol. xxiv, p. 497.), that the application of the nitrate of silver to the cavity of the larynx is not, however, to be classed among these ordinary methods; and the practice of it by Dr. Green seems to have been received with so much incredulity in the United States, that he has thought it necessary to multiply evidence as to the fact that he has introduced a strong solution of nitrate of silver within that cavity. Louis and Bellar are supposed, by Dr. Green, to have been the first to prescribe and employ topical medication in chronic laryngeal disease. They found a solution of the nitrate of silver, in the proportion of two drachms, or sometimes four drachms, to an ounce of distilled water, to be the most efficacious and harmless application. Two methods were adopted by them; the one was to saturate a small sponge attached to a bent rod of whalebone, and to manipulate so that the solution be expressed into the larynx: the other was to use a small silver syringe, with a tube suitably adapted of course without elbow, to supply the requisite. Dr. Green by these means, however, several years before the appearance of Messrs. Trouseau and Bello, had, instituted experiments, and come to a similar conclu-

361. Where the laryngeal complication occurs in the advanced course of phthisis, this practice can prove only of temporary benefit. I have been consulted in many cases of this description where it had been said to have been resorted to, but apparently either with no advantage, or with very temporary relief. However, in idiopathic or primary cases, or when the complication occurs in an early stage of phthisis, for which a rational and an appropriate treatment is prescribed, this local medication of the laryngeal complication may be employed, by one capable of performing it, safely and satisfactorily. I do not, however, believe that the appliances here advised enter the larynx and trachea once in twenty times; whatever benefit results arises from the application to the under surface of the epiglottis and adjoining parts. I have, since the commencement of my practice, trusted much in those cases to the inhalation of the weak vapour of tartar emetic, arising from the application of the embrocation so often mentioned, either around the throat and neck, or to the chest, or between the scapulae.

362. D. THE ABDOMINAL COMPLICATIONS OF PHTHISIS have been already fully considered, when remarking upon the treatment of the diarrhea (§ 328.) and of the impaired digestion and assimilation (§ 234.) so generally observed previously to, and in the course of the malady. But the functions of the liver are also not sufficiently discharged in the course of the disease; and due attention has not hitherto been directed to them. That this organ has been long disordered in cases of phthisis is shown by the nature of the organic lesions it generally presents after death (§ 118.). It has been insisted upon by an able and close observer of the causes and nature of disease (Dr. McCormac, of Belfast), that phthisis is also perpetuated, by an imperfect supply, and an insufficient digestion and assimilation of pure air in and by the lungs; consequently, the red globules of the blood are not oxygenated and assimilated to such an extent or amount as to supply the requisite. Dr. Green by the advice of Messrs. Trouseau and Bello for the elaboration of healthy bile: owing also to this cause, the carbonaceous and hydrogeneous elements are not sufficiently combined with the
oxygen of the respired air, so as to contribute to healthy assimilation and nutrition; and they consequently, under the influence of life, form morbid or adventitious products, and give rise to the fatty enlargement of the liver so generally found after death. (111)

363. The great importance of promoting the digestive and assimilating processes from the very commencement of phthisis, whatever other means of treatment be adopted, will appear from what has been advanced above; and I know of no surer means of attaining this end, than by improving the secretions and excretions by suitable medicines and food, and by removing the patient to a high, dry, and temperate air, where he may enjoy the advantages of sunshine and exercise, and avoid those causes which reduce organic nervous or vital power. In general physicians have been during the last half century, in which such wonderful advances have been made in the practical sciences, so much occupied in listening to sounds which they often could neither interpret nor refer to their proper sources — in splitting the diagnostic hairs floating before their troubled, if not already distracted, minds, in hearing what they believed even when not believing what they heard — as to be carried along by the pathology in fashion, neglecting those great views of physiological pathology which alone furnish the true basis of rational and successful practice. Whilst a murmur, a bruit, a rale, a ronchus, and every sound for which a term could be coined, and their various grades, cedemes, &c., were observed, or were feigned to be observed, and were noted, and paraded and admired, on all occasions, the conditions of the vital powers and functions, upon which both disease and recovery from disease mainly depend, were entirely neglected. But attention to these latter, to the states of the secretions and excretions, to the manifestations of impaired vital power, to the causes of this impairment, to the removal of those causes, and to the true means of restoring lost energy, as regarded a malady the most fatal, the most prevalent, the most prevalent in its prevalence, was practically discarded; and fussy manipulations, striking examinations, where such examinations and manipulations were often unnecessary — were paraded in the place of these, and of other more profound, more physiological, and more practical investigations.

364. E. Several other complications, of less frequent occurrence than the above, have been mentioned (§§ 119—123.); but the means appropriate to each will readily suggest themselves to the physician. Edema of the lower extremities (§ 120.) not unfrequently occurs in the advanced stages of phthisis, and is sometimes diminished by prescribing small doses of biphonate of soda, or of potash, with the tonic injections or the diuretics, or with the means employed for the disease. Pressure on the course of the veins of the lower extremities, by the sitting or other posture of the body, sometimes favours the edema, and even occasions a permanent obstruction of these vessels.

365. xii. Brief Remarks on some of the Means advised for Tubercular Phthisis.

— Having considered the treatment which appears the most suited to the several forms and stages of phthisis, I am next desirous to notice those medicines which have been recommended by writers for this disease, and to mention the circumstances or states of the malady in which they may be prescribed, and in which they are contra-indicated. Most of these medicines have been prescribed empirically in phthisis; for, although the treatment of the disease had assumed a rational aspect in the works of our countrymen Brown and Morton, there were few besides, even among the most eminent of medical writers, who presented us with a plan of cure which was even tolerably applicable to the stages and states of the disease; and, even amongst those who had cultivated the most the diagnosis and pathology of this malady, there were very few who recommended their favourite remedies with due reference to the states and complications of the disease, and to the pathological conditions which they had themselves described or admitted. I shall, therefore, attempt to inquire, in my brief notices of the substances recommended, into the circumstances in which either experience or the operation of these substances warrants their use.

366. Acids. Most of the mineral and vegetable acids have been employed in phthisis; but seldom with any definite object, or with a rational indication. The chief intention with which they have been prescribed in recent times is to repress or prevent hemoptysis, or to act as a refrigerant when the febrile action is considerable, and the night-sweats exhausting. They are merely palliatives — and in this they often fail, and sometimes they even render the cough harder and more severe; and, with the exceptions of the hydrocyanic and boric acid, they are injurious to the sub-inflamatory states, and in the inflammatory complications of the disease. — The acetic acid has long been employed in phthisis; and when the contra-indications just mentioned do not prevent recourse to it, either simply or in the form of raspberry-vinegar, or oxymel, more or less diluted, it is a grateful and cooling medicine, especially after hemoptysis has been considerable or excessive. In states of great exhaustion, or colliquation, when it is desirable to produce an aniseurism as well as an astringent effect, the pyroglaulous acetic acid may be given, or even a drop of the aromatic.

367. Sulphuric acid, much diluted, has been commonly prescribed in phthisis, and generally with the same object as the acetic. Bando gave it with mucilages; Jorberus with the Phellandrium aquaticum, a medicine much employed in Germany for this disease, and Portal in states of weak dilution, as a cooling drink; Rolfo and Hufeland considered it useless; but Collettach, Grant, de Haen, Home, Pothecary, Simmons, Sims, and Marx, entertained a more favourable opinion of it, especially in the form of acidum sulphuricum aromaticum, or citric et citric. Quarin very justly cautions against its use in the more inflammatory states and complications of the disease. — Weak dilutions of the nitric and the hydro-chloric acids may be prescribed, in the same states as those which admit of the use of the foregoing; and the combination of the two in some part of the former to two of the latter — when the contra-indications mentioned above are not present — and, when exhaustion, colliquation, and other symptoms of vital depression are urgent, these two may be added to the infusion of cinchona, or other restoratives, especially whenever the functions of the liver are much impaired. I have prescribed them weak.
benefit in such cases, and sometimes given the cod-liver oil on the surface of a mixture of these or of similar substances.

Hydrocyanic acid is one of the most useful medicines in this disease. It was introduced into practice by Magendie, Granville, and Elliott, who took a just view of its effects both in phthisis and in dyspepsia—complaints so intimately allied in their origins and in their pathology, as already shown. Its influence in the latter benefits the former, whilst it exerts a direct effect on the cough, without aggravating, but rather ameliorating, any complication which may appear in the course of the malady. It may, moreover, be advantageously conjoined with other acids, with the neutral salines, most of which it is incapable of decomposing, and with the great majority of other medicines usually prescribed for phthisis. Of the other acids, the most important are the citric, the benzoic, and the boracic. The citric is serviceable in the states of the disease for which the acid is given; but, either in the pure form or as it exists in lemon juice, it is most useful as an astringent or demulcent in combination with the alkalies. In these latter states it aids, with other means, in preventing, countering, or removing the morbid conditions of the circulating fluids in the advanced stages of phthisis. Benzoic acid has been frequently advised in various combinations for this disease, but has rarely been confided in alone. It is chiefly in the more asthenic and colliquiative conditions that it is at all of service. I have seen more benefit from the boracic, than from benzoic acid. Either of these acids may be given conjoined with mucilaginous, balsamic, and expectorant medicines, when these are indicated. The boracic acid and its alkaline salts—the biborate of soda and B. of potash—are not contrary-indicated by the inflammatory diathesis, and may be given in these states in which the mineral acids are inappropriate. I have found the dilute phosphoric acid of much service in the few cases in which I have tried it. It may be prescribed in doses of 20 to 40 minims in cases of phthisis characterised by vital depression or exhaustion, especially when the disease appeared to result from depressing causes, or from masturbation. For such, it may be given in the infusion of alfalfa, or of ginseng root, with or without the addition of the tincture of sambuci.

369. Aconite was first prescribed for phthisis by Portal, who afterwards relinquished the use of it. Busch gave the powder of the dried leaves in doses of two grams every two or three hours, and increased the dose until a draught was taken in the twenty-four hours. I have prescribed the powder in smaller doses in a few cases; and the extract in doses of a quarter of a grain, in others, cautiously increasing the dose; but I have ventured upon it only in the more inflammatory states as a substitute for bleeding. I cannot say that I consider it as an emetic or irritant; but Tanneur has stated it to have been. It had, however, the effect of lowering the pulse, of causing perspiration, of diminishing pain, and of affording ease; and, although I cannot view it, with the writers just mentioned, as a cure for phthisis, yet I consider it as an useful, and perhaps as a necessary, medicine in the more inflammatory states and complications of the disease, when prudently exhibited, or when its doses are increased, or its use interrupted and renewed from time to time, as circumstances require.

370. Alkalies and alkaline salts are serviceable in several states of phthisis. The former, and their sub-carbonates, were much praised by Harn, and Spalding. I have often prescribed the liquor potassae, and Brancher's alkaline solution in the scrofulous forms of the disease, with sarsaparilla, demulcients, and narcotics, and, in the protracted form, with tonics or bitters and anodynes, with temporary, and sometimes with permanent benefit. In certain states, and more particularly when the blood is probably more or less contaminated by the passage into it of morbid matters from the lungs, the alkalies are often advantageous combined with the solutions of the neutral salts, as the bi-carbonate of potassa, with the nitrate, or the solution of the acetate with the carbonate of ammonia, and with the other substances now mentioned.

371. Ammoniacum was frequently prescribed in phthisis, and often injudiciously, especially in combination with quinsy or other healing gum-resins. It should be given only in the more chronic states of the disease, and even in these with caution, and rarely with the medicines now mentioned. I have prescribed it with benefit when an expectorant was required, and when no inflammatory complication existed; but if the cough became severe or hard during its use, it was always relinquished. I generally gave it as follows:

No. 359. R. Ammoniaci 3m. tere cum Aqu. Descit. 3vss.; duas alia Vidi Antimonialis 3i.; Lig. Ammoniaci acetatis 5i.; Tinct. Conii (vel Tinct. Hyoscyami) 3i.; Syrupsu Althaeae officinalis ad 3vill., miscæ. Sic mistura, cajus capiat cochl. j. vel ij. larga, 4tis vel 6tis horas.

No. 360. R. Ammoniaci 3m. Tinct. Benzoini Comp. 30i.; Tinct. Camphori Comp. 3ae.; Aquae Fluor. Aurandi, Aquæ Sambuci, s. 3i.; Terrebras, et Syrupsu Althaeae officinalis ad 3vill., miscæ. Cicat. capiat cochl. j. amplexum, 3tis vel 4tis horas.

372. Balsams have been long in use in chronic pectoral diseases, and especially in phthisis; and although they are sometimes of service, they are as often injurious, unless they be given with great discrimination. Under this denomination the Copaiba, the Peruaria, and the tuba balsam fall more strictly; the others more correctly belong to the terebinthines and to the gum-resins, and to these likewise the older writers often extended the term. The circumstances, and the combinations in which the balsams, and even the other substances often ranked in the same category as these in phthisis, are the same as those which I have stated in respect of the exhibition of ammoniacum (§ 371.). When it is considered that these medicines, and those closely allied to them, are appropriate only in certain states of the malady, that an empirical use of them may be as often injurious as beneficial, we should not be surprised at finding them recommended by Dr. Harn, Godbold, Simmons, Burns, &c.; and de-
nounced by Fothergill, Frize, and others. The Copaiba balsam was preferred by Fuller, Hoffmann, Monro, and Gesner; but it is now seldom prescribed for phthisis. A substance becomes a remedy only by its appropriate use.—Barium, the hydrochlorate, has been recommended in phthisis by Hering and Crawford; but, although it has been prescribed by many, yet no satisfactory result has been adduced respecting it.

373. Bitters and tonic infusions, as those of absinthum, Gentian, Calumia, Chereits, &c., have been advised for phthisis by Celsius Aurelianus, Chalmers, Salvator, Rich, May, and Sears, generally also with a nourishing and digestible diet. Although too generally and empirically prescribed by these and other writers, yet these medicines are often required in the usual and more chronic states of the disease, especially with the view of removing the symptoms of indigestion so frequently attending phthisis from its commencement, and of supporting the vital powers. These infusions, moreover, may be made the vehicles, in which other medicines, whether saline, anodyne, or alterative, or narcotic, may be prescribed.

Chromates of copper, administered by Burckruius; by Marx, with nitre and hydrochlorate of ammonia, and Barnham, with potassium nitrate; it is useful chiefly as an adjunct to other more appropriate medicines, or when it is given with the object of abating urgent symptoms. In small doses it is beneficial, especially when conjoined with nitre, the spirits of nitric ether, and solution of the acetate of ammonia, in allaying febrile action and inflammatory complications. In larger doses, and combined with the sesqui-carbonate of ammonia, it is of service in the advanced stage of phthisis, in rallying the vital power and in counteracting morbid conditions of the blood, whilst it promotes expectoration; and with the extract of conium or of henbane, or with a preparation of opium, it allays irritation, both locally and generally.

374. Carbon or charcoal was formerly much employed in the colliquative states of phthisis, in dysentery, and in putro-adenyphic fevers. I have given it at an early period of my practice in several cases, but generally with camphor, chalk, cascara, and aromatics, in doses varying from a scruple to a drachm; and chiefly with the intention of correcting the fester of the excretions. Schrenkel states that Schrenkel gave it in phthisis with digitalis; and Garrett prescribed it with sulphur and the extract of the smaller centuary. I suspect, however, that whatever benefit resulted from these combinations cannot be imputed to the carbon. M. Jouwdan justly remarks, “Lorsque les théories chimiques régnent en Médecine, on attribuit au Charbon végétal puissante vertus dans la phthisie pulmonaire, la dysenterie, et surtout les maladies putrides. Le temps n’a justifié aucune des espérances qu’on avait campées à cet égard.”

375. Cascorilla was often prescribed with the same intention as cinchona and the medicines last noticed. I have given it only in the form of infusion in the more colliquative states and non-febrile forms of phthisis, and have generally made this preparation the vehicle for such other medicines as the necessities of the case suggested. Cascorilla has received the approbation of Tec-
employed in phthisis and scrofula than perhaps any other medicine. It has been praised by Quarin, Zeviani, Fothergill, Adam, Butter, Busch, Hufeland, and many others; and yet there are few more equivocal or in imperfect states of preparation, and are of uncertain. At the present day it is seldom confided in alone; and when given as an adjunct to other means is often in insufficient doses, or in imperfect states of preparation, and most persevered in for the time required to evince its effects.

330. Creosote has been recommended for phthisis by Schoren, Richenbach, Cortoni, Ramfold, and others. I have employed it, since its introduction to medical practice, chiefly as an adjuvant of other means in the last stage of the disease, and for the mitigation of the disorders of the stomach and bowels, of nausea, vomiting, diarrhœa, &c. It is also of great benefit when used to slightly impregnate the air of the apartment in which the patient chiefly resides (§ 413). Creosote, however, should not be prescribed in the cases of phthisis of a chronic and indolent state, and tonics, when the cough is dry, hard, or constRICTIVE, when a state of erythema or of active congestion is inferred, and when an inflammatory complication or active hemoptysis is present. It is chiefly in the colliquative or asthenic conditions of phthisis, that it is a valuable adjuvant of other means, and especially when the excretions are more or less fetid, and the circulation is com ITNITATED by the passage of morbid matters into it from the primary seat of disease.

381. Digitalis has been recommended by some, and praised by others, for phthisis. Indeed there is, perhaps, no other medicine which has been more generally employed in this disease, and whose operation has been less understood, than digitalis, has, in short, been more empirically prescribed. It has been sanctioned by Beddoes, Withering, Darwin, Ferrier, Spence, Fowler, Kindlæke, Macennin, Mayer, and Thomas. Dr. Drake says that citric acid counteracts its unpleasant or cumulative effects, when given in too frequent or too large doses. Whilst the above, and many continental writers, are favourable to the use of digitalis in phthisis, Breek and Bailey contend that it is injurious in some cases and useless in others. I have, however, seen some benefit derived from the infusion, prescribed at first in very large, and afterwards in rapidly diminished doses; especially in the hemoptysis and febrile states, and in the congestive and inflammatory complications of the disease.—Dulcamara was advised for phthisis by Berrébus, and afterwards by Stark, Richter, and Hufeland, who generally gave it in conjunction with the Iceland moss.

382. Emetics have been recommended for phthisis since the days of Hippocrates to the present time. Morton, Bryan-Robinson, Maryott, Simmons, Sims, Kentish, Maret, Reid, Mettenich, Swedlund, Parr, Richter, Dumars, &c., advise emetics at an early stage of the disease; some, as Reid, Bayes, and others, with a frequency which appears to be excessive; and, in particular, the Young, Clarke, Witt, &c., in a more moderate and rational manner. Many physicians in Italy, early in the present century, pretended to have cured phthisis by the exhibition of a solution of tartar emetic, in the infusion of the flowers of the sambucus nigra, or in other emollient infusions—generally three grains of the former in six ounces of the latter. A quantity, in phthisis in the last stage, was directed night and morning, and milk and water were drank freely. If diarrhœa supervened, digitalis and ippecacuanha were prescribed in small and frequent doses, with other means calculated to moderate or arrest the diarrhœas, and the emetic tartar was relinquished.

383. Emetics are often of service, especially in the early stage of the malady, and when advised as above (§§ 306. 317.); but they should be prescribed with caution, and with strict reference to the functions of the stomach and liver, and to the assimilative and vital powers. I have already mentioned those which may be preferred; but even they ought not to be given so as to impair digestion and assimilation; and if these functions be weakened by them, or in cases where this risk appears great, mild tonics and a restorative and digestible diet, aided by external application, should be prescribed. Among the emetics of a stage of phthisis, emetics are of more doubtful advantage, but even in these they may be of service. Blumenbach recommended them even in the third stage; but either in this, or in an earlier period, they sometimes constitute an important part of rational practice, especially if appropriately selected, when the digestive mucous surface appears to be loaded by sordes, when the expectoration is difficult or scanty, the breathing suffocative or oppressed, and the biliary secretion interrupted, or deficient in the evacuations. But even in these circumstances, vital power should not be exhausted by a too frequent recourse to them, and the digestive functions ought to be restored soon afterwards by suitable tonics and anodynes, as the infusion and tincture of columba, or of chereita, or of other bitter tonics, with hydrocyanic acid, comium, &c.; or with one of the vegetable extracts, the purified mace, &c., in the form of pill.—Ipecacuanha is useful in phthisis not merely as an emetic but as a nauseant, expectorant, and promoter of digestion, and as a corrector of morbid actions in the bowels, according to its dose and mode of administration. As a nauseant it was praised by Priti, Bastard, and others; and it certainly is a valuable medicine in the more inflammatory and hemoptysis states of the disease; and in the form of pill with bitter tonics and anodynes, or astringents when the bowels are much relaxed.

384. The iodide, especially the iodide of potass, have been employed in phthisis, but are appropriate only in the more chronic states of the disease. Since the discovery of iodine, the use of its preparations in scrofula had extended to tubercular consumption. The earlier prescribers of this substance, and of iodides generally, erred in giving them in too large doses, in scrofulous and other diseases, and in neglecting to conjoin them with a sufficient quantity of alkalies, whereby the irritating effects of the iodine, or the decomposition of the iodide, by the acids of the stomach, might be prevented. Thus, even when a very small dose of the iodide of potass is prescribed in a vehicle suited to the features of the case, the action of potass or the bicarbonate should be given in sufficient quantity to prevent the decomposition of the iodide. Whatever form or combination of iodine is
TUBERCULAR CONSUMPTION—REMARKS ON REMEDIES USED FOR. 1165

given in phthisis, the effect upon the digestive functions, the pulse and the cough should be watched, and every effort made to check those already present, it should either be relinquished, or the dose of it much reduced.—The Karagen Moss, or Fucus crispus, has been long employed as a popular remedy in consumption, and it has been favourably noticed by M. Bénézé, among others; although the fuel may be used as a demulcent in the disease, with some benefit, probably arising in part from the minute quantity of iodine this class of sea-weed contains.

385. The Lichen Islandicus has been very commonly used in consumptive cases by Quarin, Herchel, Hélisenius, Marx, Régnault, Richter, Schmidtman, Christion, and others. It is one of the most generally useful medicines in this disease; its bitter, demulcent, and tonic properties, disteved of exciting action, rarely proving injurious, even in the more febrile cases. Wendt, myself, and others have found it of much assistance in the treatment of this disease, and of the many medicines to which such medicines are of the circumstances of the cases require. Sachtleben recommended a decoction of three ounces each of the lichen, and of the polyastra amara, of six draams of liquorice root, and of three draams of dulcamara, to be made with milk, as a preferable mode of prescribing the lichen in consumption. The decoction of these substances is best made with water to which a small quantity of the carbonate or solution of potash is added, boiled milk being added to the strained decoction, and such anodynes, or other remedies, as the peculiarities of the case suggest.

386. Lactucaarian was much employed by Duncan, Rothammel, and François to allay the cough in phthisis and bronchitis, and was considered appropriate in the inflammatory state of the disease. It may be given under almost any circumstances with this intention, and may be conjoined with ipecacuanha, digitalis, demulcents, mild tonics or bitters, or other medicines suited to the case.

387. Lead, the acetate of, has been often prescribed in phthisis, but chiefly with the view of suppressing the expectoration, has been given either with opium and ipecacuanha, in the form of pill, or in solution, with the addition of acetic acid. These combinations of acetate have been advised by Köpp, Stark, Etymology, Ameling, Hildenbrand, Horn, and others. Weber prescribed the acetate with digitalis, myrrh, balsam of Peru, extract of belladona, and mucilage, in the form of pills. Hoffmann preferred the phosphate of lead, in the dose of a grain, to the acetate, and conjoined it with the extract of henbane.

388. Lime water and the muriate of lime were advised by Quarin, Marx, Becker, and Hoflein. Effervecent lime water (Carbara-water), is very advantageously given with milk, especially when the bowels are much relaxed. For this state of the malady not only may catechu, kino, and other medicines already recommended for it be employed, but the nitrate of silver may be given, in the form of one, two, or three grains, put into pills with liquorice powder, &c., also be individually tried.

389. Mercury with chalk, the blue pill, or Plummer's pill, will be of service, when the biliary functions are not disturbed, with soap and taraxacum, or with the compound rubarb pill, or with the aloe and myrrh pill, when the digestive functions require to be assisted. In the more inflammatory states or complications of the disease colonel may be prescribed, as advised by Bonnens; although it should be pushed so far as to produce salivation, as recommended by Rust, unless the disease be consequent upon syphilis; when the very unfavourable state of the malady may require this decided treatment. When partial pneumonitis, or pleuritis, or pneumo-pleuritis complicate phthisis, then colonel may be employed, and be beneficially conjoined with antimonials, or with ipecacuanha, or with opium, or with other narcotics. The beneficial effects of the bichloride of mercury, prescribed in the decoction, or in either of the tinctures of cinchona, in scrofulous cases, have induced me, as well as other physicians, to consider the use of this substance in the more manifestly scrofulous states of phthisis; and in some instances with much benefit; but, in my own cases, as other means were also employed, especially the external treatment about to be noticed, the amount of benefit derived from the former could hardly be determined. Schaffner and Valentinn have also given the bichloride with tonics and opium in phthisis, and, as they conceived, with advantage.

390. Myrrh and various gum-resins, especially castella, galbanum, &c., are most appropriate in the more chronic or protracted forms of phthisis, when they are attended by dyspnoea or difficult expectoration, and in females when the catamenia are difficult or scanty; or when the disease has been caused by depressing or exhausting causes. They are contra-indicated during inflammatory states and complications, and in the febrile forms of the malady; and are best suited to the circumstances of the disease which admit of chalybeates, tonics, balsams, cinchona, &c. In the form of Griffith's mixture (§§ 314. 377.), or when conjoined, as in the compound galbanum, or compound iron pill, or when further combined as with soap, extract of colchicum, or extract of henbane, they are sometimes of service.

391. The oils, especially fish oils, have only recently been employed in consumptive diseases, although they have been long previously used in other disorders. Hanel appears to have been the first to prescribe the cod-liver oil in phthisis in Germany, and Professor Bennett in Edinburgh, to whom the credit of having first recommended it is clearly due, contemporary with the earliest employment of it in this country, it was prescribed for a lady, whom I frequently saw in consultation with my friend Dr. Baird; and at that time it was not to be had in London. Mr. Mouson having procured it, at our request, from the Continent. Since then I have employed it in this and several other diseases; and have always seen more or less benefit derived from it, especially in the more usual, and in the protracted, states of phthisis. It may be given in various ways; but generally with greatest benefit, from an hour to two hours after a meal, in the dose of half an ounce or even more for an adult, on the surface of any agreeable vehicle, as of an infusion of oranges peel, or of any bitter tonic or aromatic infusion, with...
either a little acid or carbonate or citrate of an alkali, and any anodyne, &c.; or on the surface of milk, or of ginger or orange wine, &c. This oil may be taken twice or thrice daily, and in all stages of the disease. After continuing it for some days, or interrupted for a few days, and medical treatment may then be directed more especially to the digestive functions, and to the promotion of the biliary and intestinal secretions and excretions; and after such intermission, its use should be resumed and continued for a time which the state of the case and its effects will indicate.

392. All the fish oils, especially the oils from the livers of the Torsk, Cod, and other fish which I have enumerated above (§ 336.), are beneficial in phthisis, especially when they are recent, or fresh, and then they may be taken in larger quantity. The common use of fish oils in the most northerly countries of Europe probably is partly the cause of the infrequency of phthisis in those countries. The use of vegetable oils, especially olive oil, in countries near the Mediterranean, and in the north of Africa, may have the effect of diminishing the numbers of cases in those countries; and the adoption of the palm oil nut, as an article of food, in Western Africa, and of the oil for daily inunction of the surface of the body, may have a similar effect on the natives of that part of the world. It is not unlikely that other mild vegetable oils, as linseed, almond, &c., may also prove of service when taken in sufficient quantity and when judiciously conjoined with other medicines. Formerly the oil of asphaltum or of bitumen was often prescribed for phthisis, especially by Callisen, Bang, Theilenius, Haller, and others. Quain said that it was only slightly palliative, whilst Frize considered it injurious. It was probably employed then, as other things have been used recently, or are praised now, merely with the object of being, with their advocates, talked of.

393. Opium and Opiates, in various forms, have been advised in phthisis, and indeed have been condemned by others. There are, however, states of the disease which indicate the propriety of having recourse to them, and circumstances which contra-indicate their use. They are more frequently injurious than beneficial in the first stage of the disease, although Tralles has given a different opinion. Sometimes in the second stage, but most frequently in the third stage, opiates, or even the preparations of morphia, are of great service; but much of the benefit produced by them will depend upon the combinations in which they are prescribed. Marcus gave them with myrrh and Persian balsam, and, in the advanced and more chronic states of phthisis, this combination, or that with the compound galbanum pill, and the compound soap pill, will be appropriate. Pears advised opiates to be given with the carbonate of ammonia, ether, and aloes; and J. Frank Landau, with the aromatic sulphuric acid. In the third stage of the disease, preparations containing more or less opium, especially the compound tincture of camphor, the compound styryx pill, pills of ipecacuanha and opium, &c.; and, when diarrhoea is present, the opiated creasote powder, the compound creasote powder with opium, the compound ipecacuanha powder, the compound kino powder, or the combination of opium with the extract of naux vomica, or with the nitrate of silver, or with the sulphate of copper, or with the sulphate of zinc, will be found individually of service, when judiciously prescribed. When there is much debility, opiates should not be given in full doses, unless they be combined with aromatic, tonics, or stimulants; or with balsams or gum resins; and when the preparations of morphia are preferred to other opiates, then this recommendation should be especially kept in recollection, because I have seen much distress result from its neglect.

394. The Philandrium aquaticum, or water hemlock, especially the seeds and herb, has been much recommended for phthisis by Stein, Oswald, Fischer, J. Frank, Ricamier, Rosenmüller, Henning, Michaelis, &c., who have employed chiefly the powder of the seeds, in doses of ten to twenty grains, the decoction and tincture. Its action is stimulant, narcotic, and diuretic. Some of the authorities now added have given this medicine with sulphur. Lange prescribed it, after bleeding, in robust or phlegmatic cases, in goats' milk twice or thrice daily; Hesse, with nitrate of silver, in the same doses; and Robertson, with gums Arabic, thrice daily; and Hufeland, Müller, Choppa, Remer, Berrus, and Heine, in various forms and combinations, — in powder, decoction, and tincture.

395. The Polygala amara has been much praised in phthisis by Thilenius, Plenck, Colwin, Baume, Frize, &c., and is certainly to be preferred to the polygala senega, in this disease, as it is more tonic and pectoral than this latter. It was formerly much employed in consumptive diseases; but has now fallen into undeserved neglect. The root is chiefly used; and either in powder (from fifteen to thirty grains), or in extract, or infusion, or decoction, in which forms it is directed in several of the Continental pharmacopoeias. The Polygala Senega is much more stimulating than the P. amara, and is not appropriate in the more inflammatory and complicated states of many writers, and is often condemned by others. There are, however, states of the disease which indicate the propriety of having recourse to them, and circumstances which contra-indicate their use. They are more frequently injurious than beneficial in the first stage of the disease, although Tralles has given a different opinion. Sometimes in the second stage, but most frequently in the third stage, opiates, or even the preparations of morphia, are of great service; but much of the benefit produced by them will depend upon the combinations in which they are prescribed. Marcus gave them with myrrh and Persian balsam, and, in the advanced and more chronic states of phthisis, this combination, or that with the compound galbanum pill, and the compound soap pill, will be appropriate. Pears advised opiates to be given with the carbonate of ammonia, ether, and aloes; and J. Frank Landau, with the aromatic sulphuric acid. In the third stage of the disease, preparations containing more or less opium, especially the compound tincture of camphor, the compound styryx pill, pills of ipecacuanha and opium, &c.; and, when diarrhoea is present, the opiated creasote powder, the compound creasote powder with opium, the compound ipecacuanha powder, the compound kino powder, or the combination of opium with the extract of naux vomica, or with the nitrate of silver, or with the sulphate of copper, or with the sulphate of zinc, will be found individually of service, when judiciously prescribed. When there is much debility, opiates should not be given in full doses, unless they be combined with aromatic, tonics, or stimulants; or with balsams or gum resins; and when the preparations of morphia are preferred to other opiates, then this recommendation should be especially kept in recollection, because I have seen much distress result from its neglect.

396. Sasa, &c. — Besides the barks already mentioned (§§ 376, 378) others, especially the willow, the cedar, the larch, and fir-barks have also been employed in phthisis, but they are useful chiefly as tonics and astringents, and have few other virtues to recommend them. Gourraud and Schneider prescribed an extract of the middle bark of the willow in this disease; and the cedar and pomegranate barks were prescribed not merely as tonic in phthisis, but also with the object of destroying intestinal worms, with which this disease was sometimes complicated, especially in low, cold, and damp localities.

397. Sage is an old and popular remedy for coughs and colds: it was also much used in pulmonary consumption. It is by no means
TUBERCULAR CONSUMPTION — REMARKS ON REMEDIES USED FOR.

bad adjunct to other medicines, and may be advantageously combined with the decoction of
some balsams, in which form it was prescribed by QUARIN and others.

398. Salts and Saline Solutions of various kinds have been prescribed for phthisis, with the intention
of moderating the hectic and other symptoms, rather than with hopes of curing the disease, although
some may be as rationally considered capable of effecting this latter object as many other medicines which have been
employed with this expectation. Of this class of substances none are more generally useful than the
solution of the acetate of ammonium, and of the

Proc. of potash, soda, and of magnesia, are of service, either individually, or with the nitrate of potash,
and the other substances enumerated, chiefly in advanced stages of the disease, when the blood
becomes contaminated by the absorption of morbid

In similar cases of phthisis the carbonates of the alkalies are also of service, especially when with the nitrate of potash, or
with the chloride of potash, in solution or in vehicles — bitter, tonic, or demulcent — suitable to the
requirements of particular cases. The hydrochlorate of ammonium was much employed by Thiele,

399. The secale cornutum has been found very

 efficacious in arresting the hemorrhage, in the

hemoptysis states of phthisis. Dr. T——, who had been for many years subject to attacks of
hemoptysis, had been in habitual success,

to the secale, in doses of five grains, at intervals

of a few minutes, until the discharge began to cease. It was not until an advanced period of life, and when travelling on the railway, that he was disappointed in the effects of this remedy, for he always carried it with him. I saw him on his arrival in town, and prescribed oil of
turpentine. The hemorrhage returned some time afterwards, and produced suffocation. I had an
opportunity of examining the lungs. The appearance

are noticed in another place (§ 91.). The

phthisis proceeded from tuberculous absces.

Sulfur was formerly much employed in phthisis, and was prescribed either in combination with

myrrh and various balsams, gum resins, or powders, or in the form of a balsam or electuary,

prepared with an essential oil, as the oil of aniseed, or with honey or syrup, and given with such other medicines as absorbent, or narcotic — as the state of the case suggested. The anisated balsam of sulphur es-

specially, and other combinations of this sub-

stance, were strongly recommended by Ettruller,

Buch, Simm, Agricola, Rolfe, and others.

Hunold prescribed it with charcoal in the ad-

anced stage of the disease. The anisated balsam of

sulphur, the preparation most frequently used, consisted of one part of the flower of sulphur, and

four parts of the oil of aniseed, which were
digested in a sand-bath. If diarrhoea was present, the sulphur was given with preparations of chalk,
or with astringents and tonics. Sulphur has long

since fallen into disuse in phthisis; but I have seen much benefit from it in several states of the
disease, when judiciously combined and pre-

scribed.

401. Tartar emetic was prescribed by Schlegel

in small and frequent doses, and was probably

employed by him and others on account of the

apparent benefit derived from it and other anti-

monials in the inflammatory complications of the

disease. The contra-stimulant doctrine in vogue

in Italy at the end of the last century, and in France at the commencement of this, carried the
use of tartar emetic in diseases of excited action to an extravagant pitch; yet more harm than good was the result. More injury than advantage was derived from it, owing to its improper use. However, in the more inflammatory, and in the more active hemorrhagic, states of the malady, it is often of

service when given either as an emetic, or in frequent small doses, as a contra-stimulant.

402. Tussilago farfara has been for ages a

popular remedy for chronic coughs and consumptions;

and the several parts of the plant have been used in the form of infusion, decoction, electuaries,
syrups, &c. for these complaints. It was recom-

mended for phthisis by PARROIL, BROMMER, KRAMER, and others; and the mucilaginous,
bitter, and mildly tonic virtues of the plant appear to warrant their recommendation.

403. Turpentine, in the various modes of its ex-

istence, from the essential oil through the terebin-
thinate balsams to the pine-tops, tar, and tar-water, have been for ages found of benefit in various

states of phthisis, some in certain states, and others in other states. These substances, in their several modes of employment, are often of service, not only when exhibited internally, but also when employed externally, and when the much diluted vapour, or even the spirit itself, has been inhaled into the lungs. In the hemoptysis states of phthisis, when it is proper to arrest the hemorrhage, there is no remedy that is more certainly efficacious than turpentine, when exhibited in small and

frequently repeated doses, epithems of the same

substance being applied over the chest. It may

be taken in doses varying from twenty minims to

a dram every hour, or two or three hours, according to the urgency of the case; or even oftener, either mixed in honey and liquorice powder, as prescribed by GASSET and myself, and as advised in a memoir on the use of this medi-
cine, published in 1829 in the London Medical and

Physical Journal; or as directed in a case lately attended by Mr. W. BARNWELL and myself.

404. The quantity of the oil may be diminished or increased, or the frequency of the dose increased or otherwise, according to the circumstances.
stances of the case. There are almost no complications of phthisis which contra-indicate the use of this remedy, when judiciously prescribed, as respects the dose and mode of exhibition; and especially when employed externally also as hereafter recommended. The terebinthiaceous substances, in which the essential oils exist in different forms and combinations, are also beneficial when suitably prescribed. The infusion of pinn tops was praised by Cælius Aurelianus for phthisis; tar water was recommended by Bishop Berkeley for this and other diseases; and tar was given by Sims for this malady. I have had recourse to these, especially to tar and tar-water. Tar, in the form of pill, with liquorice powder, is often of great service in the colliquative states of diarrhoea, and when there is reason to fear incipient ulceration of the mucous follicles of the bowels. Tar-water, when sufficiently weak, not to be unpleasant to the patient, is also of service in this state of the disease, and in its haemorrhagic and congestive complications. Indeed there are several states of this malady, and several other diseases, in which both tar and tar-water may be very usefully employed. The injurious or rather extravagant property of many of our sea-coast countries, the conserve and other preparations of roses, by Morelly and very many other writers; the phosphoric acid, by Goëdis; the sulphate of iron, by Stanger; and taraxacum, by Schmidtman. These hardly require any remark. They may be employed under circumstances which prevent the use of other more beneficial remedies; or in conjunction with such means as have already been advised, as with the Iceland moss, digitalis, conium, &c. or with bitters, as absinthium, calumba, casenilla, arnicas, &c., when a restorative diet is required, or when digestion, flatulence, or sickness are experienced. In certain states or complications, as in those just named, the preparations of ammonia, as the carbonate, &c., or the athers, may be conjoined with other means with benefit. Of the ethereal preparations, the compound spirit of sulphuric ether, the spirits of nitric ether, and the hydrochloricum have been advised by many in the early stage of the malady. At this stage venescence, hardly amounting to more than eight or ten ounces at a time, and repeated according to circumstances and to its effects, has been recommended by Morton, Mead, Frengle, Mono, Fothergill, Salvadori, Stoll, Hoak, Farm, Chyney, and others. I have stated above (§§ 309—313) the circumstances in which the practice may be adopted; and that it should not always be accompanied with other antiphlogistic remedies, either in an early stage, or when pre-erited for inflammatory or haemorrhagic complications; for beneficial and beneficial, may be followed, in many cases, by suitable tonics and nutrients, provided that exercise be taken with due care in the open air, and that the external application be noticed (§§ 415, 416.), such as issues or sores, be kept discharging. Rush advised, for cases requiring venescence, recourse to it in preference, in spring and autumn. But this recommendation is in conformity rather with an old custom than with correct pathological inference. Rinnow, Tracy, and Ross considered that an attack of haemorrhage from the menses, rectum, or even from the lungs, beneficial, and the larger the better, and that it should not be too soon arrested, unless manifestly injurious. The opinion is certainly often correct, but the numerous exceptions should not be overlooked.

407. Various other substances have been prescribed for phthisis by eminent writers; and, although they may be of little use, further than as adjuncts to other more beneficial remedies, they may be very briefly enumerated at this place. The arum triphyllum was recommended by Burton, in the form of decoction with milk, the cardium benedictus, either in decoction, infusion, or extract with senega, by Thellius; the ergot of cantharellus, by Hoffmann; the genu arum, by Buckland, in doses of a scruple and upwards of the powder of the root, as a tonic and astrigent; the tops and flowers of hypericum, for its balsamic, bitter, and tonic qualities, by Laxner; the nosturtium aquaticum, by Porteau and Brillette; marsh, conjoined with sulphur, or various other substances, by numerous writers; the rhum radicans, by Ginon; the ruphumus, or horse-radish, by Schenck and Oslander; the marsh cantharellus, by Albert, a popular remedy; in various forms of preparation, for pectoral complaints in most rivers at the commencement of the last century have caused the complete disuse of an excellent remedy.

408. Uso ursi, in powder, decoction, and extract, was recommended for phthisis by Dr. Bourne, and subsequently by Drs. Hamilton and Davy. The tannic and gallic acids it contains, and its astrigent and tonic qualities, would justify its use in several states of this disease, especially in the haemoptysis, and in the colliquative sweats and diarrhoea which occur in the advanced stages. It may, moreover, be combined with other remedies, — demulcent, tonic and antholyne, with opiates, bitters, &c., according to the peculiarities of the case.

409. Venuection and other modes of vascular depletion, as by cupping or leeches, or by the application of these last to the anus, as insisted on by Flemitz and Laxner, with antiphlogistics, equalizers and dilatants, has been advised by many in the early stage of the malady. At this stage venescence, hardly amounting to more than eight or ten ounces at a time, and repeated according to circumstances and to its effects, has been recommended by Morton, Mead, Frengle, Monro, Fothergill, Salvatori, Stoll, Hoak, Farm, Chyney, and others. I have stated above (§§ 309—313.) the circumstances in which the practice may be adopted; and that it should not always be accompanied with other antiphlogistic remedies, either in an early stage, or when pre-erited for inflammatory or haemorrhagic complications; for beneficial and beneficial, may be followed, in many cases, by suitable tonics and nutrients, provided that exercise be taken with due care in the open air, and that the external application be noticed (§§ 415, 416.), such as issues or sores, be kept discharging. Rush advised, for cases requiring venescence, recourse to it in preference, in spring and autumn. But this recommendation is in conformity rather with an old custom than with correct pathological inference. Rinnow, Tracy, and Ross considered that an attack of haemorrhage from the menses, rectum, or even from the lungs, beneficial, and the larger the better, and that it should not be too soon arrested, unless manifestly injurious. The opinion is certainly often correct, but the numerous exceptions should not be overlooked.
not, however, be overlooked, that all these waters contain various proportions of different saline ingredients,—the oxides or salts of iron, or sulphurised hydrogen, or alkaline carbonates, being present in certain of these waters also in various proportions.

The chalybeate mineral waters are chiefly indicated in those states of the disease for which the compound iron mixture has been recommended above (§ 378.), more especially in lymphatic and phlegmatic temperaments, and when the pulse is weak, small, or slow, and the blood poor in red globules. Generally the weaker chalybeates, or the stronger more or less diluted, are most beneficial, and should be preferred for cases where their use is of doubtful propriety. The mineral waters of Aix-la-Chapelle, especially the sulphurised chalybeate, have been recommended for this class of cases: but the mineral waters of this country, of a similar composition, are equally appropriate with those; especially the chalybeate and saline spring at Harrrogate, which may be taken alternately with the sulphureous waters of that place. The mineral waters of Kissingen are also of service early in the disease, or when phthisis is threatened, especially when the several springs are employed, under judicious medical direction.

410. b. Sulphureous mineral waters are often beneficial in phthisis, especially if the composition of the several springs containing sulphurised hydrogen gas be such as may be appropriately employed for individual cases. The several springs at Harrrogate supply a sufficient variety of composition to suit the various states of different cases. The waters of Moffat and Strathpeffer are stronger in sulphur than those of Harrrogate, but they present a less variety of composition. The waters of Englishe and Barreges may also be tried, but they offer even fewer advantages than those already mentioned.

411. c. The mineral springs abounding in the carbonates of the alkalises, as well as holding various other substances in solution, have likewise been recommended for threatened and incipient phthisis, and they have been recommended by Ems, Salzter, and Viehl. These are usually most beneficial when taken with milk or with whey. The Ems waters are much praised by Bruchman and others; and the Salzter by Bang and Kramer, in this disease, especially when diluted with milk or whey. The waters of Cauterets have also been recommended by many; and those of Bonnes and St. Sauveur of the Pyrenees, have proved most beneficial in several instances which have come before me. Whatever mineral water be adopted, other means, medicinal, regi-

412. xiv. Inhalation of various fumes and vapours, chiefly medicated in various ways, and by diverse means, has been advised by many.—a. I have seen several modes of inhalation employed, and have prescribed certain of them, but without any very manifest benefit. The great disadvantage of most of these means is occasioned either by the amount of aqueous vapour thus passed into the lungs, or by the irritating or other effects produced in the air-passages by the ingredients employed. I have already noticed the subject of inhalation above (§ 324.), and when treating of bronchitis (see art. Bronchiæ § 96. et seq.); and in the opinion I have stated under this latter head a further experience has fully confirmed. I may mention, however, that the inhalation of sulphureous aether, with the vapour from preparations of conium, was advised by Dr. Pearson; of vapour containing the fumes of Burgundy pitch, by Home; of aqueous exhalations from henbane, myrrh, and "naphtha vitrioli" (sulphureous aether), by Joerdenes; of the fumes from pine-tops, and various balsams, by a number of writers; and of tar-vapour, by Chrichton and Pagdenacker. But the usual modes of inhalation, especially those in which inhalers are employed, are most objectionable and much more injurious than beneficial.

413. b. Weak fumigations diffused through the apartment occupied by the patient are much more beneficial than any mode of inhalation; and the vapour, or the weak fumes, or rather the odours, exhaled from the substances employed for the purpose of impregnating the air of the apartment, are sufficiently strong to be resired by the patient in most cases. The greatly diluted fumes or vapours proceeding from creosote, from tar, from turpentine or the several tercineinites, from pine-tops, from various balsams, from the authors, especially pyrolycineous aether or pyrolycic spirit, from cedar, and from resins, gums, &c., independent of any combination with aqueous or narcotic vapours, are generally much more beneficial and pleasant to the patient than the inhalations commonly employed. The embrocations so frequently recommended for this (§§ 321, 322, 405.) and several other diseases act beneficially, chiefly in consequence of the inhalation by the patient of the ingredients as they are evaporated, or as their dilute fumes are exhaled and diffused in the air surrounding him. A young man, who had repeatedly consulted a chief of surgery, was in an advanced stage of phthisis, completely recovered his health after he had been for a considerable period employed in the manufacture of creosote. When cough is distressing, the fumes of aether, arising from the sprinkling of one or other of these, especially of the spiritus asberis sulph. comp., the pyrolycineous aether, or pyrolycic spirit, or the hydrochloric aether, or of chloroform, on the bed-clothes of the patient or on any article more or less removed from him, will often have a very palliative effect.
benefit is derived in some cases is to be imputed as much to change of air, exercise, and regimen, as to the effects of the baths.

415. B. External derivatives, and exurities have been advised for phthisis from the earliest periods of medical history. I have stated above (§§ 296—300) that this use of the system of Tartar emetic, croton oil, etc., has been frequently resorted to in recent times; but issues and setons have been rarely employed; although the experience of numerous writers, as well as my own experience in several cases, has demonstrated their great utility. The selection of a situation in which an issue may be made or a seton inserted is often a chief difficulty in the way of either. BARTHOLOME directed an issue to be made in the buck, below the scapula; BAYLE and RIVIERE between the scapula and the upper arm; SIMMONS recommended a seton to be inserted in the nape of the neck; MONRO, PORTAL, and HILDEBRAND in the arm; ZACCUS LUSIANTUS at the edge of the pectoral muscle, near the axilla; WINTZ and HUEI preferred the same situation for a seton, or near the sternum for an issue; LESTIN also selecting these places in preference to others. Whilst these and many other authors have thus resorted to these means in phthisis, they have not considered them suitable to all states or stages of the malady. QUAIN, WINTERHAM and SEVILLE, who have been less in favour of these means than the writers just referred to, consider them worse than useless in the far advanced course of the disease and when there is much exhaustion. Having often employed them with advantage—in some instances in the family of my acquaintance with reference to the care of my own—am enabled to state, that I have generally preferred issues, kept discharging by means of a number of peas, to setons; that, when the patient is not much emaciated, some part of the breast, or over the margins of the false ribs, has been preferred; that this practice is of service chiefly in early stages, before cavities are formed, and in the more usual and chronic forms of the disease; that it is more especially beneficent in the haemoptysis and congestive complications; and that it should not be resorted to in the more febrile, debilitated, and emaciated cases, and when the signs of cavities are manifest. It ought to be further recollected that time is a necessary element in the development of the effects of this treatment; that the other means of cure, the diet and regimen adopted, should be restorative and nutritious, without being heating or stimulat ing, especially the latter, which becomes so copious; and that air and exercise in the open day, avoiding injurious exposure, should not be neglected.

416. C. Blisters, rubefacients, and embrocations (§§ 319—323.) have been sufficiently noticed. The first of these, when kept discharging for some time or frequently renewed, is often of service, and may be substituted for issues or setons when these latter will not be adopted by the patient. The embrocations which I have so often mentioned are of service, both as irritants or rubefacients, and as furnishing the best means of inhaling. Cassia, is most commonly employed, and recommended by HIPPÓCRATES, GALEN, and others of the ancients, and by PORTAL, AUGLAGNÉ, GALDEN, &c., among the moderns, are rarely prescribed; and even more, although much praised by LARREE and other recent writers, are seldom resorted to. Urtication, which was recommended by LANCE, is also superseded by other means. That purulent eruptions and purulent discharges artificially produced have more or less influence in delaying or arresting the progress of phthisis, when the disease is not far advanced, are amongst the most important facts in medical practice; but much more is required than an empirical recourse to such means. A knowledge of the cases, states, and stages of the malady in which they are likely to be of service, or at least not to be detrimental, and of the other means, constitutional, local, external, and regimen, which may be brought to their aid, is essential to success in the employment of them. That the production of a purulent discharge or the formation of a purulent eruption has sometimes cured phthisis, appears to have been known from the earliest periods of medical history. After the appearance of small-pox, it was observed that a purulent eruption in that malady often cured pulmonary consumption in an early stage, and as often accelerated the progress of this latter disease in an advanced stage. This was remarked by MENVIL, BRACHET, and others; and it has been stated by writers that phthisis is rarely observed in persons much marked with small-pox (§ 231.),—a statement which has appeared to be confirmed by my own observation.

417. XVI. States of the air were much discussed by writers from the middle of the last century until early in this, in respect of consumption, and all sorts of air were recommended for the cure of this disease. The air of cow-houses was advocated by some, of marshes by others (§ 295.). Even the mephitic air produced by bilge-water (arising chiefly from the action of salt water upon the ship's timbers) was considered by BIZON and HARROW as the cause of the benefit derived from voyaging. The use of fixed air, soon after its discovery, in the treatment of phthisis, was most unprofitably discussed by writers from 1780 to the commencement of this century; and although the influence of the carburetted and sulphuretted hydrogen, and other gases given off, may be considered by some as disposed of, yet it is still viewed as not without some favourable influence by those who believe in the good effects of marshy exhalations in threatened phthisis.

418. That fixed air contained in fluids is a useful palliation of the issue or seto, and becomes so copious; and that air and exercise in the open day, avoiding injurious exposure, should not be neglected.
warrant the belief. But this refers only to the gases impregnating fluids taken into the stomach.

419. Of much greater importance is the determination of the questions, whether or no the air in very elevated situations, or in low places, and whether near the sea, or at a distance from it, is the most beneficial because of such facts as the words—1st, What is the state or states of the air which the phthisical patient may breathe with greatest benefit? 2nd, Should the states of the air, found beneficial in certain seasons, be continued in other seasons? and 3rd, If change of such an air be found requisite, how should it be most appropriately and beneficially changed with the procession of the seasons?

420. 1st. Sea voyages were prised by Celsus, Aurelius, and others amongst the ancients; and by Grant, Savary (Lettres sur l’Egypte, t. iii. p. 8.), and many among the moderns. But it is very doubtful what share of the benefit observed proceeds from the sea air itself, or from the motions and other circumstances connected with the voyage. It is not improbable that the sea air may contain certain elements beneficial to morbid states of the Jungs, and sufficient to counteract any injurious influence which pulmonary phthisis might produce. But persons living on the sea-coast are not much more exempt from phthisis than those living inland, where equally humid states of air, within the same ranges of temperature, usually exist. A greater exemption may be experienced, but the amount has not yet been ascertained, or even an approximation to it. The ancients inferred benefit from sea air, because the voyages for the cure of pulmonary diseases were generally made to Egypt, and very probably the relief manifested soon after the arrival of patients in that country was partly at least attributed to the voyage. Although Dr. Smyth is not in favour of sea air for consumptive cases, yet I know that voyaging in the Mediterranean and in the Atlantic has been most beneficial in several cases in which I have advised it. But I agree with Celsus Aurelianus, Gilbert, Beane, Reid, and many others, in saying that in over sea voyages should be adopted early in the disease; if it be resorted to at a far advanced period, and if a very warm latitude be entered into, the disease will most probably be accelerated to a fatal issue. The doubt expressed by me above (§ 307.) of the superiority of the sea-coast to inland situations, other circumstances being equal, appears to be confirmed by the observations of Dr. Richardson respecting the climate of Nubia, of Dr. Barclay on the climate of Egypt, and of Dr. Archibald Smith on the influence of high elevation in warm climates on consumption. In Nubia, Egypt, the South of Spain, and the Andes, cases of this disease, whether attended by cyanosis or not, were remarkably benefited soon after their arrival; and a removal from the last-named place to the sea-coast was often followed by a return of the malady. From the testimony and experience of these eminent writers, and from what other sources of information have been, I infer that dry states of the atmosphere, in moderate grades and ranges of temperature, and at considerable or even moderate elevations above the sea-level, are most favourable to consumptive patients; that the places just named, and Malaga, and various other places in Syria and the East, are most to be preferred; and that, before the commencement of the hot season, Nubia, Egypt, and other places, where the temperature rises very high, should be relinquished for others which are more temperate.

421. The second and third questions are partly answered by what has been stated; for although a continued residence in these climates may not be injurious to many consumptive patients, yet it may give rise to diseases of a different nature, or may occasion complications of phthisis which otherwise might not have occurred; or it may prove too exhausting, or otherwise injurious to the patient; in many cases, if not in the majority, a change to a more temperate climate is therefore beneficial before the hot season commences; and if the change can be made to a climate both dry and temperate, it will generally prove of the greatest advantage. Patients who are subject to hemoptysis, or other states of the more or less severe form of chronic forms of phthisis, will derive very great benefit from a voyage to Alexandria, and a journey thence to Cairo and Upper Egypt, and, having resided there or in Nubia some time, proceeding thence to Syria, they may return by Malaga, or Granada, or other towns on the coast of Spain, to England; or, if it be preferred, a voyage may be made across the Atlantic early in September, with great benefit; and having crossed the isthmus of Panama, the Pacific may be traversed; and having visited Lima, a residence in the mountains of Peru may be tried at. An elevation in and in the season found most beneficial for phthisical patients. After a satisfactory residence in this locality, the patient may return to Europe by the same route as by which he went out, or by one more direct, taking care, however, to return to England about May or June. * If this plan be

* There are many places in the south of Spain that may be chosen for winter residences by persons either threatened by, or in the first stage of tubercular consumption, especially in Andalusia; and if the vicinity of Malaga, or of Granada, or of Seville be selected, other places in the above extensive province may be tried. During the warmer months, the more elevated situations on the southern side, or the southern coast of the Sierra Morea, furnish many situations which cannot fail of possessing most of the advantages required by phthisical invalids.

Dr. Mitchell (Brit. and For. Medico Chirurg, Rev. No. xxiii. p. 256.) states that “the climate of Algiers, during winter and spring, vies with that of Maccar, being as warm and steady in temperature, but drier and more bracing.”

It has been a generally-received opinion among medical and scientific men that very high elevations above the level of the sea are injurious to tuberculous consumption, especially when it is either ushered in, or attended by, or even threatened with hemoptysis. Dr. Archibald Smith’s very interesting account of the very remarkable benefit he saw, in numerous cases (see above, § 420.), derived from residing at an elevation above the sea-level of 5000 to 10,000 feet, completely upsets this opinion. This very high elevation cured physicians, and the Asante, cases of this disease, whether attended by cyanosis or not, were remarkably benefited soon after their arrival; and a removal from the last-named place to the sea-coast was often followed by a return of the malady. From the testimony and experience of these eminent writers, and from what other sources of information have been furnished, I infer that dry states of the atmosphere, in moderate grades and ranges of temperature, and at considerable or even moderate elevations above the sea-level, are most favourable to consumptive patients; that the places just named, and Malaga, and various other places in Syria and the East, are most to be preferred; and that, before the commencement of the hot season, Nubia, Egypt, and other places, where the temperature rises very high, should be relinquished for others which are more temperate.

421. The second and third questions are partly answered by what has been stated; for although a continued residence in these climates may not be injurious to many consumptive patients, yet it may give rise to diseases of a different nature, or may occasion complications of phthisis which otherwise might not have occurred; or it may prove too exhausting, or otherwise injurious to the patient; in many cases, if not in the majority, a change to a more temperate climate is therefore beneficial before the hot season commences; and if the change can be made to a climate both dry and temperate, it will generally prove of the greatest advantage. Patients who are subject to hemoptysis, or other states of the more or severe form of chronic forms of phthisis, will derive very great benefit from a voyage to Alexandria, and a journey thence to Cairo and Upper Egypt, and, having resided there or in Nubia some time, proceeding thence to Syria, they may return by Malaga, or Granada, or other towns on the coast of Spain, to England; or, if it be preferred, a voyage may be made across the Atlantic early in September, with great benefit; and having crossed the isthmus of Panama, the Pacific may be traversed; and having visited Lima, a residence in the mountains of Peru may be tried at. An elevation in and in the season found most beneficial for phthisical patients. After a satisfactory residence in this locality, the patient may return to Europe by the same route as by which he went out, or by one more direct, taking care, however, to return to England about May or June. * If this plan be
TUBERCULAR CONSUMPTION — CLIMATE, ETC., IN.

followed out for two, or three, or four seasons, at an early stage, with due precautions against infection, coast to mountain may not be equally shared in by all; but I hope, though I may think this is a fair trial, and, as you recommend navigating by Panama to the Pacific, that you will find room to recommend, on fair trial, to Euro-Americans to elevate their sights on the Andes, from time immemorial known of paramount importance in races affected with pulmonary consumption." Dr. Archibald Smith's very long and extensive experience of the diseases in this part of the new world and, especially his opinion of the greatest value on this subject. He further remarks, "I observe at length that you are aware of the effect of migration on the Chinese; and I can say that, among the thousands of this race lately introduced into Lima, I never met with an instance of phthisis. It is likely, however, that this disease will show itself in their offspring born in Peru of Indian or dark women. When the Chinese crop their hair, and take on the Peruvian dress, it is not easy to distinguish them from native Peruvians. I am informed that the opinion of the Indian races are offspring from the Mongolian, or Chinese. In this respect, in his account of his travels in Egypt and Nubia, published more than thirty years ago, has strongly recommended these countries, and especially that region along the winter residences for phthisical invalids. The more recent evidence of my eminent colleague, Mr. Barclay, fully confirms this recommendation. The very interesting account given by Mr. Barclay of the climate of the Middle and Upper Egypt, in his "Voyage," is of so important to our profession, and to phthisical patients, coming, as it does, from one whose great talent and acquirements I have long known and admired, that I quote it at this place without abridgment, of which indeed it does not admit —

"The object of this communication is to draw attention to those characteristics of the Egyptian climate by which an opinion may be formed of its curative influence. For the removal to a milder and warmer atmosphere is usually recommended. The result of both observation and experience, during five months spent in that country, is a thorough conviction that there is no accessible part of the world so well adapted for the relief of most of that formidable class of diseases to which the respiratory organs are subject. In endeavoring to express this opinion, however, I am far from affirming that all Egypt, or any part of Egypt at all seasons, fulfills the conditions required in a climate suitable for phthisical cases. On the contrary, it will be readily perceived, that no part of the Delta is at any season adapted to patients who are subject to these afflictions, nor, it may be added, to those who are either dyspeptic or rheumatic; and from the beginning of May to the end of July, the heat in every part of Egypt is too great for a European constitution weakened by disease. But in Middle and Upper Egypt, from the beginning of October to the end of April, the invalid may breathe, under a bright and cloudless sky, an atmosphere at once invigorating, temperate, and healthful, and free from all excess of humidity. The climate of other regions may be equally distinguished by one or more of these peculiarities (though even that is doubtful); but assuredly there is no other habitable part of the globe in which they are all combined in so great perfection.

"The malady for which I sought relief in a southern climate was chronic bronchitis in its most aggravated form. All the usual remittent, but external and internal, had been resorted to, and steadily persevered in, under the ablest medical advice, but with little temporary and no permanent benefit. I had tried with the same unfavourable result those places on the south coast of England which are usually recommended to invalids. The symptoms obstinately resisted every remedial measure. The chronic character of the disease was frequently exchanged for attacks of a subsacute form. These always commenced with inflammation of the pharynx, creeping insidiously down the glottis and trachea to the bronchial tubes, which became gorged with mucus throughout their whole extent; and on every spot on which the stethoscope could be planted over the lungs the mucous râle was to be heard. Dyspnoea, accompanied with loud wheezing, was at all times distressing but its nocturnal exacerbations, which invariably occurred after a short sleep, like fits of spasmodic asthma, were often so fiercely violent as to threaten suffocation. The digestive organs were deranged, I had no appetite for food, my frame was emaciated, and my strength prostrated.

"I was so enfeebled as to be unable to encounter the voyage till the month of November; and thus I lost two months of the season suitable for the residence of an invalid in that country. Yet the benefit which, by the

blessing of Providence, I reap't from that delicious climate, was most that my most ardent hopes had ventured to anticipate. On the passage outward I stopped five days at Malta, but found the heat so oppressive in the daytime, and the chills in the evening so severe, that I was glad to make my escape. The extreme humidity of the atmosphere in that island, notwithstanding its high temperature, must always render it, I apprehend, an unfit resort for a bronchitic or phthisical patient; and the great extent of the diurnal range of the thermometer, at least in winter, makes it questionable whether it is an eligible residence for consumptive patients. It is believed that an inquiry into results will not tend to give a favourable idea of its saline influence on that class of complaints. Of the climate of Alexandria I also have reason, as I shall show afterwards, to speak unfavourably. In Cairo, however, a very different climate was found; and I had not been many days there when I began to experience its effects in alleviating the irritability of the respiratory mucous membrane. The coldest season there is the latter part of December and the early part of January; and though the temperature even then is equal to that of our best summer weather, yet the evenings are somewhat chill. The following observations, made with the register thermometer and Dollond's barometer, show the temperature and the dryness of the atmosphere at Cairo during the coldest fortnight of the year —

"From these observations it will appear that, warm and equable as the winter temperature is at Cairo, the weather at that season is not free from frequent and sudden alterations. It is but in the night that there is any protection from the extreme temperature. The dusty road and prolonged exposure to the sun, the dryness indicated by the barometer in the latter case was many degrees greater than that registered on the river. The following table contains the result of the observations noted between Thebes and Aswan, the uppermost town in Egypt, and from these an idea may be formed of the winter climate in that region —

"The benefit I derived from breathing the genial air of the Thebaid was very decided. The periodical night
TUBERCULOUS CONSUMPTION — DIST. ETC., IN.

422. The diet in phthisis has been already discussed in general terms, and chiefly with respect to my own experience (§§ 299—301.), but a few authorities and particulars may be further added at this place. — a. Hypochondriasis, advanced, for phthisis, animal food to be taken in small quantity, and often, when fever is absent; and the opinion has been followed by Salviadori, May, Rush, Vogel, Rollo, and Kingslake. Animal fats, marrow, and fat meals were recommended by Lagne and Bentz. The circumstances in which these may be adopted have been stated above (§§ 299—301.).

b. A fish diet is often of service, especially in the more chronic and hemorrhetic states, or attacks, though still occurring, were less violent and of shorter duration: my breathing was greatly relieved; and my strength was so far recruited, that I was able, without fatigue, to make daily excursions, sometimes of many miles, to the monuments with which this part of the valley of the Nile is studded.

At Thebes, which for several reasons should be made the starting point of an Upper Egypt, the day temperature, from the middle of January to the middle of February, ranges from 68° to 80°, and after the latter date the heat becomes rather too great to be borne with comfort. The invalid should then commence his downward voyage, and before he reaches the latitude of Cairo, he will find the climate there nearly as delightful as that which he left at Thebes. My register during the first week of March at Cairo was as follows:—

" In a city like Cairo, with a dense population of more than a million and a half of people, and with narrow streets walled in by lofty houses, and constantly watered to lay the dust, the air can never be so pure nor so dry as in the desert. Accordingly the medical gentlemen of Cairo are in the habit of sending almost all their convalescent patients to reside for some time in the adjoining desert, to enjoy the benefit of its invigorating air. It is in the desert, therefore, that the qualities of warmth, equability, dryness, and purity, which are characteristic of the Egyptian climate in general, are to be found in the most perfect union. The soothing influence of the desert air on delicate organs of respiration, and its invigorating influence on a debilitated frame, can be appreciated by those who, like myself, have experienced its marvellous effects. It is at once balmy and bracing; and the invalid, while breathing it, feels as if he were drinking in health at every pore. I quitted Cairo for the desert of Ghizeh on the 12th of March, and took up my abode in the neighbourhood of the Pyramids; and there a sudden change came over me, as by magic. The second night I passed in the desert was marked by sound and uninterrupted sleep, and the absence of the periodical fit of dyspepsia; the third, on which I had occasioned good health, or had been exempted from the other, for more than two years. My appetite soon became enormous; both the flesh and the strength I had lost during my illness were restored; every symptom of my complaint disappeared; and at the end of a month I returned to Cairo in perfect health. The following table contains the meteorological register kept by me while I lived in the desert:—

" The only other place in Egypt whose meteorology it seems necessary to notice is Alexandria. When it is borne in mind that this city is surrounded on three sides by the Mediterranean Sea, and that on the land side it is enveloped by the Lake Mareotis, a moist atmosphere may be expected; and accordingly the degree of humidity indicated in the following extract from my register is excessive. In this respect the state of the atmosphere in Alexandria, during the early part of May, will be found to contrast remarkably with that of Cairo and its vicinity during the latter part of April, while the greater equality of temperature in the former city, both from day to day, and during the twenty-four hours, is no less observable:—

A & 3
the nuts yielding the palm oil, olives, &c., are the most likely to be of service. Grapes, both recent and dried, were praised by Riverius; pickled red-cabbage by Lange, and cucumbers with vinegar and sugar, by Schmelz, Fries, Quarin, Marx; but these last should be thus dressed with a small portion of salt added. Of oranges, lemons, limes, &c., the utility is manifest.

423. d. Milk has always received great commendation in phthisis, but writers have differed respecting which is most beneficial. Thus Zaccaria, Lysanides and Bonny prefer human milk; Aneterus, Burrellus, and Stoll, asses' milk; Dierembrecker and Velschius, goats' milk; Schenck, either asses' or goats' milk; Hippocrates, either mares' or asses' milk; and Heinrich, the whey of cows' milk. Stoll considered that asses' and human milk should be diluted, and that there are injuries in the inflammatory complications and in the last stage of the malady. Whatever may be the diet and regimen adopted, milk of various kinds, in suitable forms and states of dilution, constitutes an important part of the treatment of phthisis.

"How far Alexandria, during the months of March and April, may be a more suitable residence than Madeira or Italy for those whose complaints require a climate at once dry and liquid, equalising, is, of course, a matter for the medical profession to judge; but I do think myself sufficiently informed to pronounce it as a most unsuitable place for a bronchial case. During all the time I was there I felt as if inhaling steam; my breathing was excessively affected, and my whole system was languid and relaxed. These effects, however, by the time I had been twenty-four hours at sea, were completely dispelled, leaving no doubt whatever in my mind of the cause."

I may add, that dyspepsia is very prevalent among the European residents in Alexandria; and I was informed that cases of pulmonary consumption, though not common, do occasionally occur among the natives of the whole northern seacoast of Egypt; but the inhabitants of Middle and Upper Egypt, as far as I could learn, are entirely exempted from that fatal disease. The prevailing maladies throughout all Egypt are dysentery and ophthalmia, both induced, it is believed, by exposure of the country to the incursions of cold air.

These observations on the subject of Egyptian climate would be very incomplete if I failed to notice its influence on existing hemoptysis. Several instances of the efficacy in that respect were mentioned to me, and one very decided case fell under my own observation. A. B., a middle-aged gentleman, of a clear and florid complexion, had been for years afflicted with this complaint in an alarming extent. He had spent a winter in Italy without experiencing the smallest mitigation of his ailment. He had next been sent to Madeira, and there the malady was very greatly aggravated. He was at Malta when I went to Egypt; but, finding no relief there, he came to Cairo in the end of December, and took up his abode at the hotel at which I lodged. The effect of the change of climate was immediate. The spitting of blood ceased at once, nor did it ever recur during his stay at Cairo, which was prolonged till the end of April. He then went to the south of Spain, and remained there till the month of June, when he returned to England, apparently in perfect health, and fully resolved to spend the whole of the following winter in Egypt with the view of confirming his cure.

The translation from the climate of Egypt to that of Britain is too violent to be harrassed by one whose respiratory organs are in a delicate or dubious condition, especially as the season at which it is necessary to quit the one country is far from being equal in the other. I therefore stopped in Spain on my homeward passage, and spent for the latter part of the greater part of June in that country and in Portugal. Having heard that the air of Malaga was remarkable for its mildness, I repaired there and remained there, and surprised and surprised to find myself in Europe a climate scarcely inferior in any respect to that of the seaside of Cairo. The register I kept while there, and from which I subjoin an extract, shows a temperature which was probably only a few degrees lower than that of Cairo at the same period, while its equability was greater than I had noted anywhere except at Alexandria; and what is still more remarkable, the dryness of its atmosphere exceeds that of Cairo, and contrasts surprisingly with the humidity with which the air of Alexandria is loaded.

"The atmospheric conditions indicated by the following table are doubtless to be referred, partly to the geological structure and the physical conformation of the country around Malaga, and partly to the latitude in which it is situated. "I am persuaded that, in a temperature-relative point of view this climate of Andalusia is deserving of more attention than it seems hitherto to have received. Those who take it for granted that the climate which can be mild and warm in Europe, seem to forget that Malaga is 246 miles further south than Naples, 318 miles farther south than Rome, and 318 miles farther south than Venice; and those who have not adverted to the fact will probably be surprised to find that it is 5 miles farther south than Algiers. Both Gibraltar and Cadiz are somewhat south of Malaga, but both have a great diurnal range of temperature, and are nearly equal to Alexandria in the humidity of their atmosphere; the one standing on an elevated portion of the coast, the other on a narrow spur of land projecting into the Atlantic Ocean."

In the beginning of June I moved northward to Lisbon, but on the latter part of the greater part of June I remained there in that country and in Portugal. Having heard that the air of Malaga was remarkable for its mildness, I repaired there and remained there, and surprised and surprised to find myself in Europe a climate scarcely inferior in any respect to that of the seaside of Cairo. The register I kept while there, and from which I subjoin an extract, shows a temperature which was probably only a few degrees lower than that of Cairo at the same period, while its equability was greater than I had noted anywhere except at Alexandria; and what is still more remarkable, the dryness of its climate is subject." — *The Climate of Egypt*, by the Rev. Thomas Barclay, D.D. 1st. Edinburgh, 1854.
TYMPANITES—DEFINITION OF.

TYMPANITES. (From τύμπανον, a drum).—Τύμπανος, τύμπανον, Hippocrates, Celsus, Galen;—Tympánites, Tympánitis, Augt. Latin;—Tympánites, Sauvages, Vogel, Sayn, Cullen, &c.;—Affectio Tympánítica, Hoffmann;—Tympánite, Sennert;—Metritis, Sagar, et al.; var.;—Empyema Tympánite, Parry;—Tympánia, Plonquet—Emp. Tympánitéum, Young;—Emp. Abdominis, Good;—Hydrops siccus, Augt.;—Windacht, Trommelnacht, Germ.;—Tympánite, Fr.;—Tympánitude, Ital.;—Tympán, wind drum, or drop of air, from the abdomen.

1. CLASSIF.—4. Class, 6. Order (Cullen);—6th Class, 2nd Order (Good).—I. CLASS; L. ORDER. (Author in Preface).

2. DEFINIT.—An inordinate generation and accumulation of a gaseous fluid within the digestive canal, generally with retention of it, occurring chiefly symptomatically, either terminating acute disease, or complicating chronic affections, and occasioning great abdominal distension, and a drum-like sound on percussion.

3. I. PATHOLOGY. Tympánití is generally the result of greatly impaired vital power, as manifested chiefly through the organic or ganglial nervous system upon the digestive canal, whereby not only is the toxicity of the coats of the canal remarkably impaired, but also gaseous fluids are exhaled from the digestive mucous surface. That the air is generally contained in the canal, where it is retained either by spasm in parts of the canal near to its aperture, or by the muscular structure of the canal to expel it, cannot be doubted. It has been supposed by some writers that the air may be on some occasions exhaled into the peritoneal cavity. If this occurrence take place at all, it must result from the decomposition of matters effused into the cavity, as in cases of chronic peritonitis, or of purer peri- tonitis, or of perforation of the intestines, when some of the intestinal contents have passed into this cavity. The occurrence of tympánity from these changes are however rare; but less rare when the intestines are perforated by any of the causes of this lesion of the intestines. (See Art. Intestines, § 29.).

4. Several varieties of tympánity have been enumerated by writers of the seventeenth and eighteenth centuries, according as the gaseous accumulation has occurred in the advanced course of acute morbid processes, or chronic diseases, or the primary affections, with which tympánity is associated, furnishing the basis of arrangement. Of these it is quite unnecessary to take any notice, as such occurrences of tympánity are merely contingencies of advanced and dangerous diseases, and are merely symptoms of these, or of hysterical or uterine disorders; often, however, assuming very prominent and distressing characters, especially in the last stages of peritonitis, of purperal and malignant fevers, &c. That the air which accumulates in the digestive tube in these and various other circumstances of disease cannot arise, to any great extent, from the decomposition or retention of alimentary materials, or morbid secretions accumulated or retained in the canal, is demonstrated by the absence of these sources of the gaseous collection in the more extreme cases. We are compelled, therefore, to view the accumulation of air as the result of a morbidly increased exhalation of it from the digestive mucous surface, resulting from depressed vital or organic nervous power, in connection with lost or impaired tone of the muscular coats of the canal; this last condition, equally with the augmented exhalation, proceeding from the loss of vital power. According to this view tympánity is merely an extreme state of flatulence (see that article), the gaseous exhalation having accumulated in the former, so as to produce extreme distension, but being discharged in the latter at intervals or absorbed.

5. That this exhalation must necessarily proceed from the blood, in great measure, or in as far as it does not arise from the decomposition of alimentary matters, or of the secretions, must necessarily be inferred, particularly in the more extreme and sudden accumulation of the gaseous fluid. John Hunter and Cullen believed that the fluid was thus generated, and Majendie and German endeavoured to prove the occurrence by experiment. They included a portion of intestine between ligatures, returned it into the abdomen, yet air, nevertheless, was found in it, although it contained no materials for the generation of air. That the air was exhaled from the digestive mucous surface had long been believed in, and supported by observation and analogy. Fabricius Hildanus, Hoffmann, Portal, Vidal, Gaspard, Nysten, Merat, and many others have contended for this doctrine, and have adduced facts in support of it. Bichat has shown that freshness by the action of the sulphuretted hydrogen to the gas which collects in the bowels. The swimming-bladders of fishes are known to be supplied with air from the blood only; and Blainville, Dumas, Majendie, and others have shown that a division of the pneumatic nerves is followed by gaseous distension of the stomach.

6. Tympánitic distension of the abdomen may therefore be referred—firstly and chiefly, to the extrication of air from the digestive mucous surface, owing to the states of organic nervous endowment, or to the irritation or morbid action of matters received into the alimentary canal, as in various kinds of poisoning, or to changes in the blood itself; secondly, in a small degree from the de-glutition of air with the food or with the saliva; and thirdly, and in a very variable degree, from the decomposition or fermentation of alimentary materials, or of septic or dysentery, or of weak digestion, or when the organic nervous influence is much depressed, the quantity of air which may be formed, as shown by Dr. Hales, from the fermentation of fruit or raw vegetables in the stomach is very great.

7. According as either of these sources of gaseous collections in the digestive canal prevails—
nates, or is increased, so may the nature of the gaseous fluid be supposed to vary. The states of the blood, the nature of the ingesta, whether alimentary, medicinal, or poisonous, the seat of the collection, will severally modify the composition of the gaseous fluid. M. M. Jumine and Chevreul have shown that generally the proportions of oxygen and carbonic acid decrease, while that of nitrogen increases, descending from the stomach to the rectum. Although there does not appear to have been any analysis of the air collected in tympany, yet there is every reason to infer that it does not materially differ from that usually formed in the digestive canal, unless under the influence of acute or malignant diseases, when, with an admixture of carbonic and nitrogenous gases, and a little hydrogen, sulphuretted, carburetted, and even phosphuretted hydrogen, may severally exist in varying proportions.

8. II. The Causes of Tympany,—whether pre-disposing, exciting, or determining—are in some respects the same as those which are noticed under the head Flatulency; but they exist in the former, or are rather associated, with one or more of the following pathological states:—1st, with mechanical or other obstruction to the discharge of the gaseous exhalation from the alimentary canal; 2nd, with impaired or lost contractile power of the muscular coats of the canal; 3rd, with alterations of the blood from absorbed matters or from vital changes, affecting the absorption of gases from the air, or the generation or extrication of them from the blood; 4th, with changes in the circulation in the lungs, and in the respiratory functions. Where one or more of these conditions are present, and in proportion as they are increased by depression or exhaustion of the vital manifestations or endowments of the digestive canal, in so far will the tympany become remarkable or extreme, and the possibility of its removal be diminished.

9. The causes of tympanites, or rather the circumstances, in which flatulent distension of the abdomen chiefly occur, are pathological, or consist of antecedent disorders or most dangerous organic changes. Whilst such disorders are productive of the less severe and dangerous states, or those which more nearly approach the conditions described under the head Flatulence, the most dangerous organic changes and malignant maladies give rise to the extreme instances of meteorismus or tympany. The slighter cases of flatulent distension are produced by the nature of the food, especially by subacrid and aromatic substances, and vegetables, by indigestible and otherwise injurious articles of food, by constipation or the retention, by mechanical or vital obstruction, of the intestinal excretions, as in cases of colic and ileus, and by hysteric or urerine and spinal irritation.

10. The extreme instances of tympany occur chiefly after poisonous ingesta, more particularly after poisonous meats, poisonous fish and shell-fish, and indeed during the last and most dangerous stage of poisoning by other deleterious agents (see art. Poisons generally, and especially §§ 427—528); in the advanced stages of puerperal fevers and puerperal pisonis; in gastritis and internitis, particularly when perforation of the intestinal canal has taken place, and then air may escape into, or be developed in, the peritoneal cavity; in misplaced gout of the stomach or bowels; and in the last stage of adynamic and typhoid fevers, and of malignant continued and eruptive fevers. They also occur as terminations of fatal ilies, of hernia, of internceptions and strictures of the bowels, of lead colic, &c. Even a moderate degree of tympanites in adynamic or typhoid fevers should be viewed with alarm, inasmuch as it is an indication of ulceration of Peyer's glands.

11. III. The signs and symptoms of gaseous distension of the abdomen are very manifest, and even the seat of distension may be correctly inferred, especially when it is not extreme. A palpation and percussion, in some cases even simple inspection, of the abdomen, are sufficient to show the seat and nature of the morbid condition. When the distension is chiefly of the stomach, the region of this organ is elevated above the margin of the false ribs, and the ensiform cartilage is protruded, the lower abdominal regions being less prominent. A similar elevation of the upper regions of the abdomen exists when the colon is the chief seat of distension; but the course of the colon, from the distended cecum to the termination of the bowel, may be observed on inspection; and it is further evinced by the hollow sound on percussion, especially as the conditions of distension to the escape of flatus exists in or near to the sigmoid flexure or rectum. In the extreme instances of tympany, arising from any of the causes stated above (§§ 8—10.), the inflation is generally greatest in the small intestines, although it may be more or less in other portions of the digestive tube. In cases of hysteric, the distension is more limited, varies in its seat, and in the sympathetic sensations and pain it occasions; and, owing to the spasm and contractions, successively affecting different portions of the tube, occasions borborygmi, and the propulsion of flatus into the stomach and oesophagus. The mechanical effects of abdominal inflation are chiefly the pressure of the diaphragm on the heart, lungs, and large veins, and the arrest of the peristaltic motions of the intestine and of the propulsive efforts by which the intestinal contents are excreted. To these various abdominal effects others may be added, consisting of destitute of exchange and arrest of the several secreting excreting functions, of congestion of the lungs and large vessels, and of imperfect oxygenation of the blood, &c.
TYPANITIES—Treatment of.

12. b. The source and nature of the abdominal inflation are to be inferred chiefly from the history of the case; from the antecedent disorder; from the seat, nature, and duration of pain; from the indications furnished by percussion of the several abdominal regions, and from the state of the excreta and of the pulse and tongue, with the various constitutional symptoms.

13. The flatulent distension is generally that of the intestinal canal, and not of the peritoneal cavity, although I would not say that this latter may not in rare cases be its seat, especially if the fluids effused into this cavity undergo more or less of decomposition previously to dissolution; but it is not improbable that the instances of gas thus evolved in this cavity, as observed by Heister, Dusseau, Lieutaud, Morgagni, Portal, and others, are merely those in which the gas had escaped into the cavity owing to a perforation of the digestive canal. Typanities has been occasionally observed in most of the organic lesions affecting the biliary organs, the digestive tube, and the abdominal and pelvic viscera. It is often an attendant on Gout of the stomach or intestines.

14. c. The appearance observed in fatal cases are those of a much larger constitution, the lesions which have been very fully described under the heads Digestive Canal and Intestines. In some cases the distension of the tube has been remarkably great throughout the greater part; and in others it has been more limited; as to the Cecum and Colon (see those articles). It has rarely been such as to rupture the bowel; spasmulation of the more distended portions being more common. The small intestines, especially the ileum, are always remarkably distended by flatus, and the glands, more particularly Payne's, are often more or less ulcerated, &c.

15. iv. The treatment of Typanity is generally difficult, often hopeless, and always dependent upon the pathological conditions of which it is merely a symptom or contingent effect. In many cases it is productive of so much and so urgent distress that it becomes requisite to attempt the removal, or at least, the modification, of the symptoms, from which it results, should occupy our attention with the view of directing the means of cure to them more especially. The indications are therefore:—1st, to remove the tympanitic distension by such means as we possess, when it is distressing and most urgent; and 2nd, to subdue the pathological states upon which the distension depends, by appropriate treatment, either when this urgency is removed or does not yet exist.

16. 1. The removal of the flatulent distension of the intestines by mechanical means was first recommended by Dr. Darwin to be attempted by the introduction of an enema-pipe into the rectum, in order to remove the resistance of the sphincter ani to the passage of flatus. Trauka proposed that the gas should be removed by the air-pump; and Dr. Osborne of Dublin adopted this means, in the mode most likely to render the recommendation successful. Since the introduction of the air-pump, he introduced a gum-elastic tube of nearly three feet in length, with a button and hole at its extremity, and, having applied to it a stomach-pump, he proceeded to withdraw the gas, and was enabled to do so with few interruptions, which were speedily overcome either by shifting the place of the tube in the intestine, or by injecting warm water to clear the holes by accidental stoppage. In about an hour the abdomen was reduced to nearly the natural size." (Lent Med. Gaz. vol. vii. p. 825.) Dr. Gravies employed similar means with success in two cases. (Lent Med. and Surg. Journ. vol. ii. p. 78.) He recourse to it in one case, with temporary benefit, and have advised it in consultation in two or three instances, but in neither with permanent advantage. It should not, however, be neglected, as more or less relief is produced by it. In many of the more severe cases I have prescribed enema containing the extract or confection of rue, or asafetida, or both rue and asafoetida, and enema with oleum olivae and oleum ierubisthina, or the other carminative injections recommended for the removal of obstinate constipation.

17. Whilst the operation of these and similar means is expected, frictions over the abdomen with either of the liniments referred to in the Appendix (F. 311.) may be resorted to, and medicines may be exhibited by the mouth. When the tympany is not attended or caused by mechanical obstruction, and is to be imputed rather to a paralysed state of the muscular coats of the canal than to any other thing, there is a very frequent and habitual distres of nox vomica in small doses, or the usual carminatives, especially rue, asafoetida, capsicum, turpentine, &c., are often of service. Turpentine, either as a confection, or as a draught, with the oleum olivae, or ole. ricini, on the surface of an aromatic water, or of common gin, in cases of hysterical tympany, or of spirit-drinkers, if prescribed with discrimination, is the most efficacious, especially if enema or liniments with this substance be employed also.

18. When the tympanitic distension has arisen from obstruction in the vicinities of the colon or in the large bowels, then the injections into the latter should consist chiefly of warm, oleaginous, and aperient, and opeaceous substances. Olive oil in large quantity may be thus employed, and this oil may be taken in small and frequent doses, oleaginous frictions being also resorted to. In several instances the tympany will be relieved by the injection of dilute gaseous mixtures of hydrogen which, when rising from hysterical pica — by chawing paper in two cases, by sealing wax in one case, and by burned wax and spermaceti in another, the obstruction was removed, in all, by these means, the causes of the disorder having been made apparent, by the numerous balls of these substances, agglutinated by the mucous of the bowels, and moulded in the cells of the colon, which were voided.

19. ii. Having removed the more urgent symptoms, the Pathological conditions producing the tympany requires close attention and appropriate treatment. These conditions are so numerous and so different that it is impossible to state all that may be required to fulfill this intention. This is, however, the less necessary as the circumstances under which typanities occurs, and the pathological causes producing it, are duly considered, with the treatment required for each, in the two articles on Dilatation and Stenosis of the intestines and of other portions of the intestinal tube, Hysterical affections, colic, ileus, and on other disorders upon which tympania is often contingent. The diverse sources of this affection, and the very opposite pathological states which may occasion it, sufficiently explain the success which has sometimes followed very
URINARY BLADDER — IRRETRIBUTABILITY OF.

1. The Urinary Bladder is a musculo-membranous reservoir for the reception of the urine, until the accumulation of a certain quantity solicits the discharge of this secretion. This reservoir is situated in the hypogastric region, between the pubes and rectum in man, and between the pubes and vagina in the female. Several connections with the urinary and sexual passages, in both sexes, and its other anatomical relations, need not be noticed at this place. It is sufficient that we bear in recollection, that in addition to the disorders and lesions which are seated in it solely or chiefly, it is liable, in consequence of these connections, and of the nervous and vascular communications existing between it and other parts, to several sympathetic affections, the most important of which are those depending upon lesions of the kidneys and ureters, and upon those of the prostate gland and urethra. In all cases, therefore, when the urinary bladder appears to have been affected, the patient should be directed also to the states of these organs and passages; and not be limited to these, but be extended further and more especially to the composition and condition of the urine and of its deposits, with the several relations of digestion and assimilation.

2. I. IrretrIBUTABILITY OF THE BLADDER. — CLASSIFICATION. — II. CLASS; III. ORDER. (See Preface.)

3. DEFINITION. — A frequent and urgent desire to micturate, independently of febrile symptoms and of inflammation, and of organic lesion of the urinary bladder and prostate gland.

4. I. SYMPTOMS. — A person otherwise in good health feels an urgent desire to void his urine after very short intervals, and if the desire be not gratified, either he is incapable of retaining it, or he retains it with great difficulty, and with more or less pain. The effort at micturition is sometimes attended by pain in the glans or under the frenum, and by such frequent and acute calls that the quantity passed at each call is very small. These latter symptoms are most frequent in old or aged persons, and in those who have been addicted to masturbation or sexual excesses, in whom the prostate is more or less tumid or enlarged. Hysterical persons are often liable to this disorder; but in these the urine is more copious and pale, and contains less than the usual proportion of solid ingredients, the nature of which is not altered. When irritability of the bladder has continued long — the organ having for a long period cease to be distended by the accumulation of urine — the capacity of it becomes permanently accommodated to the quantity of its contents, and incapable of containing more than two or three ounces.

5. Mr. Coulson, in his admirable work on Diseases of the Bladder and Prostate Gland, remarks that, notwithstanding the completed state, if there be no stricture or disease of the prostate, the paces of the bladder are often thinner than natural; and that it would seem that protracted irritation produces absorption of part of the substance of the organ. Opportunities of examining after death the bladder of persons who laboured under this affection in its idiopathic form are...
URINARY BLADDER — IRRITABILITY OF.

very rare. Mr. Coulson examined the body of a gentleman of a nervous temperament, long a sufferer from this disorder, who was carried off by disease of the lungs; but he could not detect the least alteration in the appearance or structure of the bladder, or of any of the urinary organs.

6. i. The causes of this disorder require recognition in each case which comes under treatment. The patient, or the aged, and next the very young, are more liable to irritability of the bladder than youths or the middle-aged; but the causes producing it in the aged are generally very different from those occasioning it in children. The nervous temperament, weak, irritable and anxious dispositions, and gouty and rheumatic persons are most predisposed to it. Those subject to chronic dyspepsia, to nervous giddiness, tremors, or to scaly eruptions, are often also afflicted with this complaint.

When it occurs in females it is sometimes referable to injury from pressure, either during pregnancy or in parturition, or to disorders or lesions of the uterus, ovaria, or vagina. It may be occasioned in both sexes by hemorrhoids or irritation of the rectum by ascarides, or by chronic states of dysentery. It may occur, in a slight form, even independently of hysteria, in males as well as in females, from self-pollution, or from irritation of the spinal nerves increasing the organic sensibility of the bladder.

7. a. The most frequent causes are probably those which are referable to the states of the urine, arising either from the nature of the ingesta, or from the changes consequent upon primary or secondary assimilation. It has been well remarked by Dr. Prout, in his celebrated work, that cases of irritable bladder, depending on functional derangement of the kidneys, usually result from the unnatural properties of the urine. All deviations from the normal condition of the urine, whether in deficiency, or in excess or in kind, are recognised by the containing organs, and may prove a source of irritation in the bladder. "Hence, whenever the urine is very dilute or very concentrated, or is preternaturally acid or alkaline, or contains any unnatural ingredient, the urinary organs in general, and the bladder in particular, though perfectly healthy and not morbid, and the individual has no peace until the unnatural secretion is discharged. In such cases the fault lies, not in the bladder, but remotely in the kidneys and assimilating organs." (Op. cit. p. 366.)

8. The use of various fruits, ripe or unripe, especially by children, and even by adults, and disorders of digestion and of assimilation, occasioned by these or by other causes; the elimination from the blood of unwelcome substances, conveyed into it from the organs of digestion, which are subsequently altered or unaltered by the kidneys; the excessive use of alkalies, or of those combined with the vegetable acids, and alkaline states of the urine from these or other causes; and the prolonged use of acids, or of the nitrate of potash, or of the oxide of potassium, or of other diuretics,—may severally occasion this complaint.

The irritability of the rectum, and morbid states of the urine, caused either by unwelcome food, by unripe fruit, or by impaired assimilation, or by spinal affections, or by rickets, are the most common causes of this affection in children. Mr. Coulson met with cases in children which were removed by a constriction of the orifice of the prepuce as hardly to admit the point of a probe; circumcision cured the complaint. When irritability of the bladder occurs in this class of patients about the periods of detumescence, it may generally be imputed to disorders of the digestive organs, and to consecutive alterations of the urine. The complaint of irritability with paralysis of the bladder is not infrequently met with in children (§ 36). 10. c. Symptomatic irritability of the bladder is much more common than the idiopathic disease. Granular and other organic lesions of the kidneys are generally attended, especially during the night, with frequent and urgent desire to evacuate urine; this excretion being always more or less morbid even from an early period. Diseases of the prostate gland and of its vicinity, organic, inflammatory, or malignant very generally, and strictures of the urethra not infrequently, are accompanied with this complaint. Indeed, strictly speaking, irritability of the bladder is merely symptomatic, either of disease of some adjoining or some closely related organ, or of morbid conditions of the urine; and this may be the case even in those considered purely nervous, or most devoid of manifest structural change.

11. iii. The diagnosis of this complaint is often of importance; and nothing tends more to determine this than a careful examination of the urine. Irritability of the bladder will not be mistaken for diabetes, if the quantity and quality of the urine be ascertained. Although irritability is a symptom of inflammation of this viscous, yet it is necessary to ascertain its independence of inflammatory action; and this is to be inferred chiefly from the absence of those local and constitutional symptoms characterising cystitis, either in an acute or chronic form. The absence of pain in the region of the bladder, and of frequency of pulse or of other febrile symptoms, especially towards evening, will indicate the independence of the recent state of the complaint of acute inflammation; whilst the more chronic state of irritability will not be imputed to chronic inflammation of the bladder, if the constitutional powers of the patient be excited and impaired by it. The dependence of the complaint upon disease of the prostate gland may readily be ascertained by an examination per rectum. Not only, however, may there be irritability, but also pain of the bladder, without any manifest disease of this viscous; the mischief being confined to the kidneys, chiefly in the form of calcific of these organs. Instances of this kind are adduced by Morgagni, Prout, Coulson, H. J. Johnson, and others, and have come under my own observation. Dr. Prout remarks that, in certain renal affections in particular habits, even where the urine is not very unnatural, it is confined chiefly to the neck of the bladder; but where the urine is actually diseased, and especially when it is alkaline, we may be certain that the kidney is functionally, and if the patient be of a scrofulous habit, and the case of long standing, very probably organic in the rectum.

12. iv. Treatment. — a. In recent cases, the states of the general health and of the urine will frequently indicate a successful treatment. Where the urine is very acid, or scanty, or foetid, as
red sandy deposit, and when the complaint appears in connection with either gout or rheumatism, then bicarbonate of potash may be given, with or without the nitrate of potash, in tonic or bitter infusions or decoctions; the carbonates of soda and of ammonia acting inappropriately, the former owing to its favouring the formation of urate of soda, the latter to its influence in generating urea and uric acid. Mr. Coulson states that great relief will sometimes be obtained from cupping on the perineum. This will be more especially the case if any congestion of, or vesicular dilatation to, the prostate gland be present. Liquor potasse, prescribed in bitter infusions, with benzene or conium, or with small doses of colchicum, in the gouty or rheumatic disease, is also of great service. Where the potash, in either of the states now mentioned, is not productive of relief, magnesia may be given so as to preserve the bowels in an open state, an occasional dose of equal parts of the compound infusions of gentian and sena being also taken.

13. In cases which manifest a nervous character, or which seem to be results of abuse of the sexual passions are especially required, or in combinations already mentioned, or with the mineral acids; as the infusion or decoction of cinchona with the nitro-muriatic acids, and with benzene or conium, or with a few drops of tincture of opium, or with the compound tincture of camphor. The mineral acids may also be given with the decoction of parina brava, or of uva ursi, or with the infusion of buchu, and with the additions just mentioned. I have prescribed the tincture of the muriate of iron in calumba or quassia, and anodynes, with benefit, for cases of this kind. Mr. Coulson remarks, that the decoction of uva ursi and the infusion of wild carrot seeds will occasionally give great relief; but that no medicine is so generally successful in irritability of the bladder as the infusion of cinchona; and he adds that, from time immemorial the buchu leaves have been held in great esteem by the natives of the Cape of Good Hope as a remedy for irritations and for urinary affections of the urethra, bladder, prostate gland, and rectum, and also for rheumatism, indigestion and gravel. The natives of the Cape and the Dutch are partial to the spirit of buchu, made by distilling the leaves in the drags of wine, and call this spirit buchu brandy; and they use it for all chronic diseases of the stomach and bladder, especially colic, spasms, &c. A tincture of buchu is ordered by the Edinburgh and Dublin Colleges; and half a drachm to a drachm of it may be given for a dose. In these and similar cases of irritability an opiate suppository, or a starch emulsion containing from one to two drachms of syrup of poppies, or about thirty drops of tincture of opium, may be administered at night; or a pill with opium, or benzene, and extract of colchicum, shortly before bed-time.

14. When this complaint is symptomatique of granular or other organic bladder's or of enlargement or other lesions of the prostate gland (see those articles), then the treatment must be based on the primary and chief malady. When it is connected with the gouty or rheumatic disthesis, or with either of the scaly eruptions, then the bicarbonate of potash, or the solution of potash, and small doses of the iodide of potassium, in equal parts of the compound tincture of cinchona, and of the fluid extract of sarapisarum, with one of the narcotics already mentioned, are often beneficial. If the urine becomes alkaline, or if the iodide appear to perpetuate the irritability, the allantoin-like acid should be relinquished. In this state of the disease, colchicum may be conjoined with the above, or even a small quantity of opium may be added to them. In most cases, especially when the nightly rest of the patient is much disturbed, an opiate in some soothing form should be given in the evening or at bed-time.

15. In cases which manifest a nervous character, or which seem to be results of abuse of the sexual passions are especially required, or in combinations already mentioned, or with the mineral acids; as the infusion or decoction of cinchona with the nitro-muriatic acids, and with benzene or conium, or with a few drops of tincture of opium, or with the compound tincture of camphor. The mineral acids may also be given with the decoction of parina brava, or of uva ursi, or with the infusion of buchu, and with the additions just mentioned. I have prescribed the tincture of the muriate of iron in calumba or quassia, and anodynes, with benefit, for cases of this kind. Mr. Coulson remarks, that the decoction of uva ursi and the infusion of wild carrot seeds will occasionally give great relief; but that no medicine is so generally successful in irritability of the bladder as the infusion of cinchona; and he adds that, from time immemorial the buchu leaves have been held in great esteem by the natives of the Cape of Good Hope as a remedy for irritations and for urinary affections of the urethra, bladder, prostate gland, and rectum, and also for rheumatism, indigestion and gravel. The natives of the Cape and the Dutch are partial to the spirit of buchu, made by distilling the leaves in the drags of wine, and call this spirit buchu brandy; and they use it for all chronic diseases of the stomach and bladder, especially colic, spasms, &c. A tincture of buchu is ordered by the Edinburgh and Dublin Colleges; and half a drachm to a drachm of it may be given for a dose. In these and similar cases of irritability an opiate suppository, or a starch emulsion containing from one to two drachms of syrup of poppies, or about thirty drops of tincture of opium, may be administered at night; or a pill with opium, or benzene, and extract of colchicum, shortly before bed-time.

16. In cases which manifest a nervous character, or which seem to be results of abuse of the sexual passions are especially required, or in combinations already mentioned, or with the mineral acids; as the infusion or decoction of cinchona with the nitro-muriatic acids, and with benzene or conium, or with a few drops of tincture of opium, or with the compound tincture of camphor. The mineral acids may also be given with the decoction of parina brava, or of uva ursi, or with the infusion of buchu, and with the additions just mentioned. I have prescribed the tincture of the muriate of iron in calumba or quassia, and anodynes, with benefit, for cases of this kind. Mr. Coulson remarks, that the decoction of uva ursi and the infusion of wild carrot seeds will occasionally give great relief; but that no medicine is so generally successful in irritability of the bladder as the infusion of cinchona; and he adds that, from time immemorial the buchu leaves have been held in great esteem by the natives of the Cape of Good Hope as a remedy for irritations and for urinary affections of the urethra, bladder, prostate gland, and rectum, and also for rheumatism, indigestion and gravel. The natives of the Cape and the Dutch are partial to the spirit of buchu, made by distilling the leaves in the drags of wine, and call this spirit buchu brandy; and they use it for all chronic diseases of the stomach and bladder, especially colic, spasms, &c. A tincture of buchu is ordered by the Edinburgh and Dublin Colleges; and half a drachm to a drachm of it may be given for a dose. In these and similar cases of irritability an opiate suppository, or a starch emulsion containing from one to two drachms of syrup of poppies, or about thirty drops of tincture of opium, may be administered at night; or a pill with opium, or benzene, and extract of colchicum, shortly before bed-time.

17. In cases which manifest a nervous character, or which seem to be results of abuse of the sexual passions are especially required, or in combinations already mentioned, or with the mineral acids; as the infusion or decoction of cinchona with the nitro-muriatic acids, and with benzene or conium, or with a few drops of tincture of opium, or with the compound tincture of camphor. The mineral acids may also be given with the decoction of parina brava, or of uva ursi, or with the infusion of buchu, and with the additions just mentioned. I have prescribed the tincture of the muriate of iron in calumba or quassia, and anodynes, with benefit, for cases of this kind. Mr. Coulson remarks, that the decoction of uva ursi and the infusion of wild carrot seeds will occasionally give great relief; but that no medicine is so generally successful in irritability of the bladder as the infusion of cinchona; and he adds that, from time immemorial the buchu leaves have been held in great esteem by the natives of the Cape of Good Hope as a remedy for irritations and for urinary affections of the urethra, bladder, prostate gland, and rectum, and also for rheumatism, indigestion and gravel. The natives of the Cape and the Dutch are partial to the spirit of buchu, made by distilling the leaves in the drags of wine, and call this spirit buchu brandy; and they use it for all chronic diseases of the stomach and bladder, especially colic, spasms, &c. A tincture of buchu is ordered by the Edinburgh and Dublin Colleges; and half a drachm to a drachm of it may be given for a dose. In these and similar cases of irritability an opiate suppository, or a starch emulsion containing from one to two drachms of syrup of poppies, or about thirty drops of tincture of opium, may be administered at night; or a pill with opium, or benzene, and extract of colchicum, shortly before bed-time.

18. A sudden and violent attack of pain in the region of the bladder, extending along the urethra to the glans, with either involuntary expulsion or retention of the urine.

19. This disorder is most commonly symptomatique, either of stone in the bladder, or of gonorrhoea, especially when this latter is treated by injections; or of organic disease of the kidneys, or of parts adjacent of the kidneys. Dr. Fothergill remarks that it may be caused by acid urine, by abscess of the kidney, by ulceration or other disease of the prostate gland, bladder, &c., or by retention of urine, or by gout, or by venereal excesses. Irritating diuretics, cathartics taken internally, the application of blisters, hysterics, masturbation, the irritation of ascendants in the
rectum, dysentery, or tenesmus may severely excite an attack. When it is connected with gonorrhoea or the treatment of it, then the sphincter vesica is thereby either irritated or inflamed, and spasm supervenes as soon as urine passes into the bladder.

21. B. The sudden and violent attack of pain in the bladder, characterizing this complaint, is attended by a constant desire to void urine, without the ability to do so, and the agony felt during these attacks is excessive. The contraction of the bladder excites the muscular costs of the rectum, and occasions also a desire to evacuate the bowels, or more or less tenesmus. Mr. Coulson remarks that the closure of the ureters at their vesical extremities has arisen to dilatation of these ducts and of the pelvics of the kidneys, and to serious changes in the kidneys; and that, after an attack of spasm, from which the patient has apparently recovered, it sometimes happens that a new train of symptoms appears, indicating the injury which the tubular and secreting substance of the kidneys has received. Frequent attacks of spasm also sometimes injure the tone and contractility of the bladder so much as ultimately to induce a partial or more complete paralysis of the organ (§ 27).

22. C. The diagnosis of spasm of the bladder is not difficult; it may, however, be confounded with inflammation; but in this latter the pain is constant, commences with uneasiness, and gradually becomes more and more severe. Spasm occurs suddenly; the pain is violent and constricitive; whereas in inflammation the pain, when greatest, is either lancinating or throbbing, and is attended by more or less febrile action, of which the former is generally exempt. In both the urine is usually retained, or passed in the latter in very small quantities, and after remarkably short intervals. Spasm may, however, be associated with inflammation of the mucous coat of the bladder, as spasm of the coats of the colon is associated with inflammation of the mucous coat of the intestine. In such cases the spasm is only a symptom aggravating the character of the inflammation, febrile symptoms more or less manifestly attendant on it.

23. D. The treatment of spasm of the bladder will appear from the above to depend chiefly upon the pathological state occasioning it. If it be consequent upon inflammatory action, either of the sphincter vesica, upon suppressed gonorrhoeal discharge, upon the use of irritating injections, or upon inflammation of the bladder, bleeding, according to the grade of morbid action and habit of body of the patient, should be prescribed, either by veneration, cupping, or by leeches, and be repeated if required. The warm bath, fomentations, cooling sponging, and diaphoretics should follow when indicated; and demulcents with anodyne, emollient enemata with anodynes or narcotics, &c., should also be prescribed. If the complaint supervene on gonorrhoea or the use of injections, the above treatment is appropriate; local bleeding, however, generally proving sufficient.

24. If spasm of the bladder occur in the gouty diathesis, or upon the suppression of a paroxysm of gout, or as misplaced gout, the regular form of the disease should be solicited by means of mustard podiuvia, and mustard poultices to the feet, whilst the soothing and anodyne remedies above mentioned are exhibited. In cases of this kind, as well as in many others, magnesia and sulphur may be taken, with small doses of celestium, of camphor, and of opium; and if the former be given in decided doses so as to act upon the bowels, a more rapid effect will be produced upon the spasm than by any other mode of administration. If the state of the urine occasion or aggravate the spasm, appropriate means should be used to correct this state.

25. When the disease is symptomatic of a calculus in the bladder, or in the kidney, or passing the ureter, the warm bath, fomentations, demulcents, emollients, and narcotics, or anodynes, taken by the mouth and administered in enemata, are generally of service; but when the calculus is in the bladder these means are only of temporary benefit,—permanent relief must be looked for only from the surgeon. Cases of spasm affecting chiefly the sphincter of the bladder, and causing retention of urine, are generally symptomatic of irritation or of disease of adjoining parts, and are relieved by the tinctura ferri sesquichloridi taken in doses of ten to twenty drops in water every quarter of an hour, or by a suppository containing the extract of belladonna, or by a belladonna plaster applied over the perineum, whilst the emollients and anodynes already advised are taken internally. Mr. Coulson recommends a poultice containing powdered camphor to be applied over the perineum, or a liniment composed of camphor and opium; and states that emollient enemata containing some of the watery extract of opium often afford instant relief.

26. III. PARALYSIS OF THE BLADDER.—Class:—I. Class; II. Order. (See Preface.)

27. DEFINIT. — Partial or complete loss of the contractile power, and of the organic sensibility, of the bladder; often also with loss of power of the abdominal muscles, whereby the urine is partially or completely retained.

28. I. HISTORY. — Paralysis of the bladder, whether partial or complete, whether temporary or permanent, depends on loss of power, either originating in the organ itself, or affecting it consecutively upon injury or disease of the spinal chord, or of the brain, or of their membranes. A partial form of paralysis sometimes occurs as a symptom of extreme debility or exhaustion in the course of acute or chronic maladies, as of typhoid or atonic fevers, of hectic, and of the last stage or organic diseases. In these circumstances, the contractility and organic sensibility of the bladder is more or less impaired, and the power of the abdominal muscles to aid by their contraction the explosive efforts of the detrusor urinæ, is equally lost.

29. b. In some cases the loss of power in both is general and complete, and this state of the disease, especially in its advanced or protracted form, may be attended by a constant dribbling of the urine, owing to the over-dilatation of the bladder having overcome the resistance of the neck or sphincter vesica. Thus incontinence of urine is superadded to retention, and the latter is sometimes mistaken for the former. In such cases examination of the abdomen and region of the bladder, or the introduction of a catheter, will disclose the state of matters; and strict attention should be paid to the excreting functions of the urinary organs in all fevers and constitutional maladies.
30. Paralysis of the bladder, giving rise to retention, may occur on gradually, especially in advanced age; either in consequence of disease of the kidneys, or of the prostate or urethra, or after a prolonged neglect of evacuating the bladder or the suppression of the desire to evacuate. In these circumstances, however, the paralysis and the retention may be at once complete. Although this form of the affection is most frequent in aged persons suffering from disease of other parts of the urinary apparatus, yet it may also affect the middle-aged, especially when the desire of evacuation has been long suppressed; the consequent over-distension having overcome the power of contraction, the abdominal muscles either failing to expel the urine, or expelling it only partially. In these and similar circumstances a frequent desire to micturate occurs, and after expulsive efforts made by the abdominal muscles a very small quantity only is expelled; and this state may be mistaken for a form of irritability of the bladder; but, upon a strict examination of the abdomen, or upon the introduction of a catheter, a large accumulation of urine is found in the vesic. In some persons, even of middle age, a more or less marked state of paralysis is consequent upon impaired health caused by anxiety, fatigue, excessive application to business and neglect of calls to micturate, or by venereal excesses or masturbation. When these latter causes have existed, a state of complete or incomplete tabes dorsalis supervenes, with manifest weakness of the loins and lower limbs; and if relief be not obtained, paraplegia, with complete paralysis of the bladder, ultimately results. In both this and the immediately preceding cases, as well as in some others, the over-distension of the bladder, or the distension of it to a certain extent, occasions a frequent desire or effort to evacuate the urine, and a small quantity only is passed, the power of contracting further being lost, or the contractions of the abdominal muscles being sufficient only to expel that small quantity. In such cases the catheter is often required.

31. In paralytic diseases of the spinal chord and brain, and their membranes, occasion the most complete and severe instances of paralysis of the bladder; more especially lesions seated in the spinal chord or its membranes, and whether in the cervical, dorsal, or lumbar regions. In this class of cases the effects produced upon the bladder and upon the state of the urine are different, or vary more or less with the amount of injury or disease, or with the rapidity of progress of the latter in the nervous centres; but they are generally remarkable according to the severity or danger of either. At first, or immediately after the occurrence of those, the urine may be more or less acid, and free from mucus; but especially after injury of the spinal chord it soon becomes alkaline, turbid, and ammoniacal, evincing this state at its discharge; and when it cools it deposits much adhesive mucus. After a short time phosphate of lime is found in the mucus, which adheres to its surface when it comes in contact with blood. The urine collected in the bladder is altered, either during the process of secretion, or during its retention in the bladder; and is generally changed in the following manner. The urea is converted into carbonate of ammonia, which irritates the mucous surface of the bladder and causes the exudation of much viscid mucus. The neutral triple phosphate of magnesia and ammonia contained in the secretion form prismatic crystals, and present different degrees of transparency. The inflammation of the bladder consequent upon this paralysis of the bladder, caused either by injuries or disease of the nervous centres, exerts itself from the mucous to the other coats of the organ, if the patient live for some time; and the parietes become thickened and incapable of contraction; the urine requiring to be drawn off, and always presenting a foetid and alkaline character. The question in these cases is whether the change in the urine is owing to the altered nervous power of the kidneys, or is it the result of retention in the bladder? From some attention which I have paid to this question I conclude that the change in the urine takes place primarily and chiefly in the kidneys, owing to the loss of that portion of nervous power which the spinal nerves convey to the renal ganglia; and that it is increased during the retention of the urine in the bladder, the paralysed state rendering this viscus more prone to inflammation, and to the more rapid supposition and progress of the changes consequent upon inflammation.

33. As this state of disease proceeds, the pain or uneasiness of the neck of the bladder and glans penis at first experienced subside and ultimately disappear, although distension may continue or increase. The desire to pass urine is not expressed; and whilst the local symptoms subside the constitutional become aggravated. The pulse is much accelerated, thirst is increased, and restlessness and anxiety of mind are augmented. The fur on the tongue is thicker, deeper, and darker coloured. Delirium supervenes, with a urineous odour of the perspiration, and stupor or profound coma supervenes, and the patient dies in this state; the complaint being, perhaps, mistaken for typhus fever, if due attention have not been directed to the states of the urinary functions and bladder. Patients, especially those advanced in life, when attacked by fever, owing to the congested states of the nervous centres, may experience similar changes in the urine, and a similar paralysis of the bladder; and if this unfavourable complication of fever be overlooked, it rarely fails of being the chief cause of a fatal issue.

34. Paralysis of the bladder occurs chiefly in the aged, and although in them, as well as in some younger persons, it may be favoured or caused by the states of the spinal chord or of its membranes, it is most frequently consequent upon disease of the prostate gland or neck of the bladder, or of the urethra, causing over-distension of the organ. When this complaint affects females, especially from the decline of life, it is generally connected with hysteria, or with the advanced stage of spinal congestion (hysterical paraplegia) caused by uterine irritation. I have seen several cases of hysterical paraplegia, where a surgeon was required to draw off the urine, the complaint having been imputed to masturbation. When it occurs in the males it is either a symptom of pregnancy, or of injury experienced during labour or delivery. In the fourth month of pregnancy, or about that time, or near the period of confinement, retention of urine may occur, and if it be neglected a paralysed state of the bladder may supervene from distension.
results may follow retroversion or anteroposterior prolapse of the uterus. Imperforate and obstructed catamenia from this cause are occasional in this complaint.

Hysterical paralysis of the bladder is well known to Sir B. C. Boodes, and very justly in cases, to be owing to defective efforts of the bladder.

He remarks that, in the first instance, that the nerves are rendered incapable of the stimulus, and that the solution is itself wanting; and this correctness is observed in other affections of the bladder. "As the distention in the bladder begins to be uneasy, and at last actual pain; and as soon as this happens, the bladder begins its contents. If not relieved by means shorter, the hysterical retention of urine is short duration; but if the catheter be had to the natural cure is prevented, and the patient may be indefinitely prolonged. "The rule," Sir B. Boodes adds, "in the treatment of these cases, is to interfere but little;" a rule is not without exceptions; for, in a case where the bladder has been very much irritated, there is its power of contraction, and the patient endeavours to micturate. Under these circumstances, the bladder requires to be obtained.

The affection which sometimes occurs in particularly delicate boys, and which is caused by the discharge of urine during sleep has variously explained: by some it is supposed to be irritability of the bladder, by others a morbid state of the urine, caused by this viscus, and by some to paralyse the neck of the bladder, occurring during sleep. That this last condition may obtain is not unusual, as the affection is not infrequently associated with prolapse of the rectum after a more or less deficient tonic contraction of the bladder. It may, however, depend, in different cases, under the assumption of all these conditions in different degrees, the state of the bladder may have in its share being ascertainment by the examination of the urine.

The treatment of paralysis of the bladder is constitutional, and local; but in the latter, the latter should precede the former, especially as the immediate relief of the patient is the best obtaining. I must refer to surgeons, and especially to the able and precise arguments of Mr. Colton, in his work on the bladder, to the present situation of Mr. Colton, in his work on the bladder, &c. A. The constitutional treatment must chiefly depend upon the individual cases, upon the pathology and occasioning this disease; but in general, and particularly in old cases, medical treatment, surgical appliances, and frequent introductions of the catheter, quired during the life of the patient, however, may be made of strychnine, increased to 1 grain, and carefully observed effects on the nervous and muscular apparatus, by means of the extracts of the bladder, in doses of a quarter of a grain, increased to one grain, given twice or thrice, and combined with the aloes and a little purified extract of ox-gall, or III.

with the compound galbanum pill. I have also prescribed terebintine embrocations, or, if placed over the loin and sacrum. In the extreme majority of cases, and especially in aged persons, serious lesions supervene in the kidneys in the pelvis of these organs, and thus complicate and further aggravate the disease, and render recovery altogether hopeless.

38. B. Hysteric paralysis of the bladder is not infrequently caused by masturbation, and a moral discipline is required, although it may not prudently be either suggested or enforced, unless with the utmost discretion. Indulgence and sympathy, on the part either of friends or of the physician, should be withheld, and the most noxious anti-hysterical medicines should be exhibited, especially aconite, turpentine, &c., both by the mouth and in enemias. In a case where this affection was rather simulated or feigned, than actually present, I recommended, in the hearing of the patient, the actual cauter by to be applied to the sacrum; but the complaint vanished soon after mention was made of the remedy, and directions given as to its employment.

39. C. The paralysed or relaxed state of the neck of the bladder in children, noticed above (§ 36), generally disappears as the constitutional powers of the patient improve. I have found tonics, stimulants, emetics, and stimulating embrocations applied over the loins, the spine and sacrum being sponged every morning with a strong solution of salt, of great service. The patient should sleep on a thin mattress, covered with a waterproof cloth. Change of air, sea-bathing, or sponging with sea or salt water, where the plunge bath causes alarm, and exercise in the open air, are also beneficial, and are almost essential in these cases.

IV. INFLAMMATION OF THE URINARY BLADDER. — SYN. — Cystitis, (from Cystis, a cyst or bladder); Sauvages, Vogel, Cullen, &c.; — Inflammation vesicae, Seinert, Hoffmann; — Cawana Cystitis, Young; — Empressa Cystitis, Good; — Ure-o-cystitis, Cystite, Phlegmonous; — Inflammation de la Vesie, Fr.; — Entzündung der harnblase, blasenentzündung, Germ.

CLASS. — 1. Class. 2. Order (Cullen); — 3. Class. 2. Order (Good); — 3. III. 1. Order (Author, in Preface). DEFIN. — A sense of pain in the region of the urinary bladder, increased on pressure, with a frequent desire to micturate, generally preceded by chillis or rigors, and attended by inflammatory fever.

40. I. STRUCTURES AND PARTS OF THE BLADDER. — Inflammation of the bladder most frequently commences in the mucous coat, to which it may be limited, or it may extend to the external coats. When it thus commences it may be circumcised, or it may affect all the coats. When the former obtains, the part covering the neck of the bladder and the cystic triangle is most commonly affected; but inflammation, whether limited to the mucous surface or affecting the other coats also, or even the whole perivascular layer of the organ, generally commences in this situation, owing to the irritation of salubrious matter, of calculi, &c. The imperfect emptying of the bladder, especially in connection with engorgement of the prostate, the confluence of this...
URINARY BLADDER—INFLAMMATION OF—DESCRIBED.

part to the prostate and urethra, the liability of the extension of inflammation to it from these parts, and the participation in irritation of the rectum and vagina, also account for the more frequent commencement of cystitis in this part. From the extension of disease, cystitis may be concomitve upon inflammation of the rectum or vagina, upon urethra, or upon haemorrhoids; and it is often consequent upon and complicated with inflammation of the prostate. In addition to these modes of commencement, cystitis may primarily attack the peritoneal covering of the fundus. This is comparatively a rare occurrence. The fundus of the organ is much less frequently the seat of the disease, particularly at an early stage, than the neck of the bladder and the parts situated posteriorly between the sphincter and entrance of the ducts. When inflammation commences in the peritoneal coat of the organ it usually arises from the extension of the morbid action from adjoining parts, as the rectum, cecum, colon, or omentum. Uro-cystitis has thus been observed in the course of colitis or inflammatory dysentery, of peritonitis, and of inflammation of the generative organs in females; and the connection of these maladies has often been rendered manifest by examinations after death. Inflammation may also attack all the coats of the bladder either primarily or consecutively. The former is of rare occurrence, the latter is much more frequent, owing to its extension from the mucous or serous surface of the organ, and to injuries and operations.

41. Uro-cystitis, with reference to its seat, may be viewed, 1st. As to its limitation to the mucous surface of the organ; 2nd. As to its extension to the coats forming the parietes; 3rd. As to the part of the vesic a most frequently affected either primarily or secondarily; 4th. As to the nature of the morbid notion; 5th. As to its consequences; and, 6th. As to its complications. Each of these heads will be considered in detail.

ii. INFLAMMATION OF THE MUCOUS SURFACE OF THE BLADDER. — SYN.—Blepharorrhagia vesiculae, Swelling; — Desjaria mucosa, Cullen; — Desjaria vesicalis, Fritsch; — Desjaria vesicule, Suli; — Pyuria mucosa, Sauvages; — Cystorrhoea de la vessie, Fr.; — Mucous-cystitis (Author).

42. Inflammation of the mucous coat of the bladder generally proceeds from the common causes of inflammation, and from those which are usually productive of cystitis (§§ 84 et seq), especially the extension of inflammation of the urethra to the neck and internal surface of the organ, the use of irritating injections, of irritating diuretics and aphrodisiacs, the irritation of calculi, &c. This form of cystitis is of frequent occurrence, and immediately follows the use of the enemata from it to the most acute to the most chronic, owing to the distension and habit of body, age, and mode of living of the patient, and to its causes.

43. A. The acute form of the disease is characterized by severe pain, increased by pressure, sense of heat or tension in the hypogastric region, and uneasiness in the perineum, and by frequent urgent calls to discharge the urine, attended by difficulty and increased pain. These symptoms are often preceded by chills, hiccups, or rigor, and are followed and attended by febrile reaction and its usual concomitants. Sometimes neither chills nor hiccups are felt, especially when the disease has extended from the prostate gland to the urethra, the pain in the region of the bladder, and the frequent desire to urinate being the invading symptoms. The urine is passed often and in small quantities, with much smarting heat and repeated efforts. It is generally acid, of a deep lemon or orange colour; at first clear, but in a day or two numerous small shreds of lymph or mucus are seen floating in it. Sometimes the urine is reddened and turbid, and deposits a thick sediment, consisting chiefly of a mucous-puriform matter. In a few days the irritation and febrile disturbances are diminished; the severity of the pain in the region of the bladder is abated; but often, even when this abatement is well marked, the quantity of mucus or of mucous-puriform matter in the urine is increased. The local and symptoms of irritation, and the frequency and the difficulty of urinating, generally more or less subside about the same time.

44. B. The consequences and terminations of acute mucous-cystitis vary with the severity, the causes, and the nature of the attack, and the constitution and other circumstances of the patient. If the inflammation proceed no further than the mucous surface of the neck of the bladder and of the parts in the immediate vicinity, the above symptoms diminish gradually, and the disease terminates in resolution. But very different consequences occasionally ensue. If the inflammation be very acute, it may rapidly extend to all the tissues of the organ, and even partially to others in the vicinity, the disease becoming extremely dangerous or even fatal. In this case it passes into a state of uro-cystitis, to be noticed hereafter. More frequently, however, the acute inflammatory symptoms gradually subside, especially the febrile action, but the local ailments persist for some time, or continues with greater obstinacy, the disease becoming chronic.

45. C. CHRONIC INFLAMMATION OF THE MUCOUS SURFACE OF THE BLADDER sometimes supervenes upon the acute, as just stated; but it often occurs in a primary form,—a. In this latter case its invasion is slow, and it is often accompanied by a febrile disturbance, unless the inflammation assume an intermediate grade between the acute and chronic. Sometimes the febrile action is very slight or remittent, and the local symptoms are chiefly remarkable, especially irritability of the bladder, pains in its region, or at the extremity of the urethra, previous to and at the time of passing the urine. This excretion furnishes, especially as it cools, a mucous or mucous-fibrinous deposit, of various shades of colour in different cases, and often an ammoniacal odour. A sense of weight in the perineum, or of heat in the bladder and along the urethral canal, and especially of a shooting pain to the anus are also often experienced. The discharge of mucus in the urine is more or less considerable,—hence the term catarrh vesiculae,—but varies much in different cases and at different times.

46. a. Some hypogastric case is slight; but in old cachectic subjects, and when complicated with disease of the kidneys or of the prostate, or with both, it is often dangerous, or even proves fatal. In this latter state, or when the disease has gone on to ulceration, the heat in the bladder and urethra amounts to scalding, the desire to pass the
urine becomes more frequent and urgent, and the efforts more violent or straining. The expulsion of the last portion of urine is more or less painful and difficult. The urine, becoming stagnant, owing to the obstruction caused by clots of mucus or fibrous exudation lodged in the passage, pain is felt at the extremity of the penis, in the perineum and anus, sometimes in the loins and thighs. There are thirst, costiveness, or irregularity of the bowels, or, in intense or restless, wasting of flesh, and loss of strength.

47. a. The mucus discharged in the urine varies much in quantity and appearance. It is sometimes small, at other times or cases it is so great as to amount to pounds in the twenty-four hours. In small quantity the urine is rendered turbid or flaky by it, and settles to the bottom of the vessel. It is occasionally stringy,ropy, or of a lumpy or viscid consistence. The urine is generally acid early in the disease, but it becomes neutral or alkaline as the mucus secretion is increased. When acute mucous-cystitis passes into the chronic, the quantity of mucus becomes considerably reduced; in some cases extremely great, forming glairy orropy streaks in the urine, which are afterwards deposited. When the disease has not been of long duration the mucus in the urine is generally whitish-grey or yellowish-grey, tenacious or stringy, insidious, and presenting no distinct appearances of pus. But in the more chronic or obstinate cases a purulent matter is evidently present, mixed with, and often more or less predominating over the mucus. In these cases the morbid matter is less abundant, less tenacious, of a yellowish colour, more readily miscible with the urine, and is sometimes streaked with thin bloody filaments. It is also sometimes fixed, is not so readily deposited at the bottom of the vessel as the mucus secretion, nor is it so tenacious. It does not form albuminous flocculi when boiling water is poured upon it, nor does it coagulate, or but imperfectly, when boiled. When these appearances are seen in cases of considerable duration, ulceration of the mucous surface, affecting chiefly the follicles, and the extension of inflammation to the connective cellular tissue may be inferred. This inference will be still more fully borne out if there be slight fever or a remittent or intermittent or hectic form, constant pain in the organ, emaciation, restlessness at night, and the undoubted presence of pus in the urine, with more or less alkalinity.

48. a. Pus may be distinguished from mucus not only by the above appearances, but by its being miscible with the urine, which it renders opaque. If the urine contain pus as well as mucus, the former is deposited upon the latter, and is yellower in tint, and opaque, the mucus being transparent. The microscope aids the diagnosis in these cases, by showing the presence of pus-globules of the diameter of 10,000 an inch. If the urine be send the nucleus of the pus-globule may be seen without the aid of reagents; but, as it is more frequently alkaline, the addition of a drop of acetic acid will bring the nuclei into view by rendering the corpuscle more transparent. A correct picture of pus is sometimes produced by a large quantity of triple phosphate in the urine. But the nature of this is shown by its solution in nitric acid, and by the shape of the crystals under the microscope. When the urine containing pus presents an acid reaction, pyelitis may generally be inferred; when it is alkaline cystitis may be considered to exist. Purulent urine is frequent, owing to the obstruction caused by more or less abundant sediment is formed; the supernatant fluid is often of a greenish-yellow tint, and contains albumen.

49. Dr. Proust states, that in the advanced stage of the disease the mucus in the urine is less abundant; it becomes opalescent and of a greenish-yellow tint, and can in part be easily diffused through the urine, rendering it glairy or opaque, or milky like pus, the morbid matter being in fact mucopuriform. The urine is now generally deep coloured, or serous, or albuminous, having an ammoniacal colour and effervescing with an acid. In this latter case there is an excess of carbonic acid of potash or of soda in the urine, derived from the serum of the blood. “When these symptoms have continued for a longer or shorter period, the urine becomes scanty, still more high coloured, and occasionally even acid; the mucus and even the pus gradually ceases to be apparent and of a greenish tint; and after a short period of comparative peace the patient expires.”

50. a. Intermediate grades of mucous-cystitis, between the acute and chronic states of the disease, are occasionally met with in practice. These have often been termed sub-acute. They are to be distinguished by more or less of the symptoms already adduced; generally all of them, but in different degrees of severity, and attended by remittent or hectic febrile action. They may occur primarily or follow the acute, which may subside into the sub-acute and ultimately into the chronic state, terminating at last in ulceration and thickening of the organ, or some other structural lesion. The chronic form of the disease may even pass into the acute, although not so often as the converse, either having presented an intermediate grade of morbid action, or having, owing to some exciting cause, suddenly assumed the acute form. In this latter case the extension of inflammation still further should be dreaded and guarded against.

51. e. The duration of mucous-cystitis is extremely various: it may be from one month—it being seldom much less in women—to two or three months in the sub acute, to several months to two or three years in the chronic. It depends entirely on the cause, the age, and constitution of the patient, on the degree to which the inflammation may have extended to the other parts of the viscus and to adjoining parts, and on the complications the disease may have presented. The same circumstances also influence the prognosis and treatment (§ 83. 89.).

iii. Inflammation of All the Coats of the Bladder. — Cystite profonde, Cloquet; — Cystitis vera — true Cystitis.

52. This form of cystitis is not often met with as a primary disease. It much more frequently supervenes on one or other of the forms of mucous-cystitis, and it occasionally occurs from the extension of inflammation from contiguous visceræ; as from inflammation of the uterus or ovaria or Fallopian tubes, or of the rectum, colon, caecum, peritoneum, omentum, &c.; from extensive hemorrhoids, and from disease of the prostate. It will be seen that true cystitis, in some of these consecutive states of occurrence, are mentioned in...
the peritoneal surface of the fundus, and that it extends to all the coats. It is indeed extremely rare for an effusion of serum to be found in this part behind the structure of the bladder, unless when it supervenes in the manner now alluded to.

53. True Cystitis is thus more frequently secondary or consecutive, and but rarely primary.

But, whether originating in the one way or in the other, it is as severe and dangerous a disease; and, it is often to its consequences, is but too generally followed by the most serious effects. While the mucous coat only is the seat of inflammation the functions of the muscular coat is seldom affected in such a manner as to allow inordinate accumulations of urine within the viscous, unless the disease is attended by an obstruction to the discharge of the urine by associated disease of the prostate or urethra, or by the impecunuação of a calculus or fibrous clot in the neck of the bladder.

When, however, these obstructions occur, the inflammation of the mucous coat soon extends to the other coats; the previous irritability of the muscular coat is overcome by the distension consequent on obstruction; and rapidly passes into almost total paralysis or inanability of contraction, one of the most dangerous states of the organ in cystitis.

54. When true cystitis follows mucous-cystitis or carunculus vesicae, the abundant mucous or muco-purulent secretion which characterised the latter is either much diminished or ceases altogether. This arises from the transfer of the inflammatory action chiefly to the more external coats of the bladder, and the diminution of it in the surface, which was formerly its only seat. The occurrence of this change has led Dr. Penny to think that the inflammation of all the coats of the viscous is of a different kind from that of the mucous coat; but I infer that the difference consists merely in the different functions of the parts affected in both these forms of cystitis.

55. True Cystitis presents various grades of activity, from the most acute to the chronic. The pathological states through which the disease passes, and the consequences to which they lead are also diverse, and not always referable to the violence of the attack; but are dependent upon a number of circumstances connected with the cause, with complications of the case. Thickenings of the coats of the bladder, owing to an infiltration of an albuminous serum into the connecting cellular tissue, is very frequent, especially when the inflammation is subacute or chronic, or has extended from the mucous coat and is dependent upon obstruction to the discharge of urine or the presence of calculi. In these cases the distension of the bladder is a frequent occurrence; and even when this form of the disease is primary, and is not accompanied with obstruction to the discharge of urine, a loss of the power of the muscular coat, and consequent retention of urine, is a frequent attendant upon it. Although true cystitis affects all the coats of the bladder, a part of the organ may be more particularly affected by it than the rest, especially the parts near the neck, and extending thence to the ureters.

This is especially the case when the disease has followed an effusion of serum in this part; in such cases, when the peritoneal membrane is often lost on the cause of the use of the catheter, by lithotomy, menstruation, or other operations.

56. Acute Cystitis.—a. The symptoms of this state of the disease are, generally, after chills or fever, severe pain in this part behind the pubes; a sense of uneasiness in the perineum, heat and tenesmus, and heat and smarting in the course of the urethra. The patient has frequent calls to pass urine, which are always attended by more or less difficulty, often amounting to dysuria. The urine is at last expelled by drops, with much smarting, scalding, and pain, and ultimately with unavailing efforts to discharge it. When the symptoms arrive at this pitch much anxiety and tension of the abdomen are experienced. The distended bladder rises above the pubes, and the hypogastric region is very tender. The frequent calls to pass the urine and the dysuria may mislead the physican, a large quantity of water accumulating and causing injurious distension of the bladder before the circumstance is suspected. This accumulation may be explained by the irritableness of the sphincter vesicae, and the tumefaction of the inflamed parts having distributed the outlet of the bladder, and by the want of due action in the muscular coat, owing to the inflammation in which it and the other coats are involved. Hence it is thrown into frequent and inefficient action, a portion of urine is often passed, but, as soon as it reaches the irritable and inflamed parts immediately below the sphincter, spasm of these parts, and of the sphincter itself, takes place, which the contractions of the fundus are unable to overcome. The secretion of urine proceeding, distension so great as to destroy the powers of reaction results, and complete paralyse of the muscular coat supervenes. If in this state a portion of the urine pass off, it is owing to partial relaxation of the sphincter for a moment, and to the position admitting of the discharge by gravitation. This difficulty of voiding the urine and the consequent accumulation are not owing to the muscular coat of the bladder only, for in many cases the parts near the neck of the bladder are chiefly affected; the tumeffaction of these being so great as nearly to obliterate the canal, and mechanically to obstruct the flow of urine and the introduction of the catheter. In complications of the disease, with enlarged or inflamed prostate, this peculiarity of the case; a circumstance tending materially to influence the prognosis. Independently of this complication there is every reason to infer, from the nature of the morbid secretion and structure of the parts, that this swelling contributes its share with the other lesions to the production of this very unfavourable symptom. In cases of cystitis produced by injuries of the spine the paralytic state of the muscular parts of the bladder is the cause of the accumulation of urine and of the consecutive inflammation; but in other cases the inflammation is the cause of the retention and of the loss of muscular power, as above stated.

57. When the disease has reached this stage, and the accumulation in the bladder is manifest, the symptoms soon run on to a dangerous height, if relief be not soon afforded by medical or surgical treatment. The patient is disfigured; the pulse is very frequent and hard; the tongue white and loaded; the appetite is lost; thirst is great; costiveness with frequent calls to stool, painful tenesmus, and difficulty of passing a motion, especially when the
URINARY BLADDER—Inflammations of the.

Disease is seated chiefly about the neck of the bladder, or is complicated with disease of the bladder, as frequently is the case, especially in old men, are also experienced. In these cases, and in others proceeding from some irritation acting in a special manner on the bladder, as often the cystitis has arisen from the improper use of caustic irritants, the presence of calculi, &c., the urine which is passed is often sanguineous, or contains a considerable quantity of blood.

58. The disease, having reached the state now described, will often evince signs of diminution, or rapidly present those of a still more dangerous character. If accumulation of urine and overdistension of the bladder have been prevented, and the treatment otherwise judicious, the former will generally be the result. But when the bladder still continues over-distended, great prostration of strength, with extreme restlessness, takes place; the pulse becomes small, frequent, intermitting, constricted, and at last weak and scarcely perceptible; the skin is hot and dry, afterwards moistened with a urinous or fetid perspiration; the tongue is dry, the thirst extreme; and to these sometimes supervene cardialgia, vomiting, hiccough, shortness of breath, or even delirium, sometimes convulsions, coma, and death.

59. b. Cases of true cystitis occasionally occur wherein little or no urine accumulates in the bladder, owing to the inflammation and consequent tumefaction of that part of the vescus surrounding or in the vicinity of the opening of the ureters into it, or to the effusion of coagulable lymph having entirely shut up their outlets. In these cases inordinate distension of the ducts and pelvis of the kidneys must occur, and, in addition to the above symptoms, those of dangerous disease of the kidneys and suppression of urine supervene; especially fulness, pain, and tenderness in the loins, numbness of the limbs, vomiting, constant hiccup, cold or urinous perspirations, rigors, subcutaneous tenderness, coma, &c.

60. c. When cystitis has followed the healing of old eruptions or ulcers, or the sudden stoppage of secretions, the disease may assume the form of the catarrh, or flor albus, or if it have arisen from the displacement or metastasis of rheumatism or gout, or if it have attacked persons of these dispositions, the several tissues of the bladder are liable to be affected nearly at the same time; but the symptoms are generally less severe than in the strictly primary and phlogistic form of the disease, and more frequently assume a sub-acute form, or some grade intermediate between this and the chronic form next to be described.

61. d. The duration of the disease in persons of the phlogistic diathesis, and at an early age, often is extremely short. It may resolve itself as much as the catarrh, or flor albus, or if it have arisen from the displacement or metastasis of rheumatism or gout, or if it have attacked persons of these dispositions, the several tissues of the bladder are liable to be affected nearly at the same time; but the symptoms are generally less severe than in the strictly primary and phlogistic form of the disease, and more frequently assume a sub-acute form, or some grade intermediate between this and the chronic form next to be described.

62. c. Terminations of Acute Cystitis.—True cystitis terminates—1st. In resolution, with a gradual amelioration of all the symptoms; 2nd. In the chronic state, with relief of the most urgent symptoms, and continuance of a dull pain, unsteadiness, and tenderness in the region of the bladder, dysuria, &c. (§ 65 et seq.); 3rd. In suppuration, when the disease is very acute, this issue generally occurring within twenty-four hours after the disease has reached its acme; 4th., and very rarely, in gangrene; 4th., and still more rarely, in rupture of the viscera.

63. (a) Suppuration is preceded and attended by pain and throbbing in the region of the bladder or behind and above the pubes, and occasionally referred to the seat of the rectum; by hemorrhages, chills, or rigors, followed by baths of heat, and sometimes by perspiration. There are often also painful tenesmus, costiveness, and fever. The urine afterwards has a turbid purulent appearance, or contains a whitish-yellow matter, sometimes streaked with blood, and has the odour characteristic of pus. In many of these cases the purulent secretion proceeds from the internal surface of the bladder; but small abscesses formed in the parietae of the viscus have opened internally and furnished this secretion. This latter is more frequently the case when the parts near the neck of the organ are more especially affected. Cloquet has recorded several instances of this occurrence, as well as of another, more unfavourable, when the abscess is formed more exteriorly, and makes its way externally to the bladder, into the loose adipose cellular tissue at the bottom of the pelvis. If, in such cases, the patient survives, the abscess ultimately points in the perineum, or near the margin of the anus. Abscess of the bladder is seldom so situated as to break into the perineal cavity. In all cases of abscess of this viscus the danger is great, particularly in the latter cases.

64. (b) Gangrene may supervene in the most acute cases, or in carcinoides, the catarrh, or flor albus, or if it have arisen from the displacement or metastasis of rheumatism or gout, or if it have attacked persons of these dispositions, the several tissues of the bladder are liable to be affected nearly at the same time; but the symptoms are generally less severe than in the strictly primary and phlogistic form of the disease, and more frequently assume a sub-acute form, or some grade intermediate between this and the chronic form next to be described. When cystitis has followed the healing of old eruptions or ulcers, or the sudden stoppage of secretions, the disease may assume the form of the catarrh, or flor albus, or if it have arisen from the displacement or metastasis of rheumatism or gout, or if it have attacked persons of these dispositions, the several tissues of the bladder are liable to be affected nearly at the same time; but the symptoms are generally less severe than in the strictly primary and phlogistic form of the disease, and more frequently assume a sub-acute form, or some grade intermediate between this and the chronic form next to be described.

M. Cloquet thinks that the rupture may occur without the previous sphenekation, from the distension, the greater tension of the bladder, and the deficient support of its parietae at this situation. Admitting that ruptures of the bladder are generally in the fundus, yet they are less to be imputed to want of support in this situation and to greater tension, than to previous ulceration and deficiency of vital cohesion characterising the advanced stages of acute inflammation, although these circumstances may contribute to the event. But very few of the ruptures of rupture that occur depend upon previous sphenekation, which is an extremely rare occurrence in this disease.

65. B. Chronic Cystitis.—When the acute form of true cystitis has not terminated completely in resolution, it frequently passes into a chronic state of the disease. But this form may occur from any cause.
commencement, and, appearing in a mild state, it is often neglected, and hence becomes an enduring disease. As in other inflammations, cystitis is observed of every intermediate grade of severity, from the least to the most chronic, according to the nature of the exciting and concurring causes and the peculiarities of the individual. The consequences resulting from the subacute or chronic forms of cystitis also vary with the severity of the attack. When the chronic is merely a continuation of the acute in a less severe degree, the nature of the disease is manifested by the persistence of the local symptoms especially, which are of a nature readily to be recognised and understood; and are chiefly those already adduced, but in a milder form.

66. When chronic cystitis occurs primarily its accession is sometimes slow, and scarcely so severe at first as to excite the anxiety of the patient. In other cases it is of a much more marked character, and more nearly approaches a subacute or an acute form. But in general it is characterised by permanent pain referred to some part of the vesica, by frequency, by urgency, attended by difficulty, as if occasioned by stricture of the urethra; by the presence of mucus or purulent matter in the urine; by tenesmus at stool and constipation; by slight fever, especially in the evening, and sometimes by fever of a remittent or intermittent form; by a loaded tongue; by inability to retain much urine at a time; and by an exacerbation of some or of all the symptoms after fatigue, exposure to cold, or efforts of regimen, especially after drinking spirits, vino, or malt liquors. These symptoms vary in degree, and one, more, or even all of them are more severe the more nearly the disease approaches a subacute or acute form.

67. The duration of this form of cystitis varies, according to the severity of the symptoms, from two or three months to as many years, or even longer. An acute or subacute state may supervene upon the chronic and shorten its duration; or the same result may follow the extension of disease to adjoining parts and the presence of serious complications. When it arises from calculi in the bladder, or from disease of the prostate or urethra, thickening of the walls of the viscous are common consequences. It may, when it approaches the acute or subacute forms, terminate in abscess, in ulcerations or perforation; or give rise to other lesions by extension of the inflammation to adjoining parts, as noticed in respect of the acute disease (§ 63.).

68. C. Ulceration of the urinary bladder may result from any one of the forms of inflammation of the mucous coat of the organ already noticed, but most frequently from the subacute, chronic, and most protracted states. It may, however, also follow the acute form and the more chronic states of true cystitis. It is often difficult to decide as to the existence of ulceration; but, when disease of the bladder has been of long duration, the pain severe and continued, with a frequently recurring desire to micturate, and an increasing difficulty and pain in passing the urine, then the existence of this lesion should be suspected, and, if the urine aseptic, the appearance stated above (§ 48.), especially if it contains pus streaked with blood, it need not be doubted. Ulceration of the bladder may take place differently: it may commence in the mucous follicles, especially in the more chronic cases; or it may follow the acute form, lymph being first exuded from the inflamed surface and subsequently detached, leaving the most acute to the most chronic, according to the nature of the exciting and concurring causes and the peculiarities of the individual. The consequences resulting from the subacute or chronic forms of cystitis also vary with the severity of the attack. When the chronic is merely a continuation of the acute in a less severe degree, the nature of the disease is manifested by the persistence of the local symptoms especially, which are of a nature readily to be recognised and understood; and are chiefly those already adduced, but in a milder form.

69. When the ulceration is seated or commences in the follicles, peroration of the bladder may result, the disease having assumed most frequently a chronic form. When ulceration or destruction of the mucous coat follows acute cystitis, all the coats forming the parietes of the organ rapidly become implicated, and the disease soon terminates fatally. The more limited states of ulceration, especially when commencing in the follicles, may perforate the void the urine, and by reaching the peritoneal surface, occasion the exudation of lymph, by which the bladder becomes united to adjoining parts; thereby preventing the escape of urine or forming a fistulous opening into some other viscous. In this manner a fistulous communication may be formed between the fundus of the bladder, the sigmoid flexure of the colon, or the rectum, or the ileum, &c. When a fistulous opening is thus formed between the bladder and any portion of the bowels, feces may pass into the bladder, unless the opening be formed between the under surface of the bladder and the rectum, and then the urine is usually voided with the feces. Fistulous communications between the bladder and the rectum are more frequent, especially in females, than between the former and other portions of the intestinal canal. When communications are formed in this situation, either by ulceration commencing in the bladder or in the rectum, an abscess below the reflected portion of the peritoneum often forms, owing to the inflammation of the connecting cellular tissue caused by the urine or by the feces. Mr. Coulson (op. cit., p. 140.) has recorded some interesting cases of fistulous openings between the bladder and intestines to which I may refer the reader. Ulceration and perforation are always attended by hypertrophy or thickening of the coats of the bladder, whether they be consequent upon mucous cystitis or the more chronic or subacute states of true cystitis. When the ulcer is seated in the posterior and inferior part of the bladder, it may penetrate the coats so that the urine will pass into the cellular tissue between the bladder and rectum, producing the most destructive effects.

70. iv. Complications of Cystitis.—One or other of the forms of cystitis may be associated with some other disease or structural lesion. These diseases may be the causes of the inflammation of the mucous coat of the bladder, as well as its complication. This is especially the case with gonorrhæa, gleet, stricture of the urethra, syphilis, calculus in the bladder, rheumatism, gout, &c. Gonorrhœa often induces a severe and chronic form of mucous cystitis, the discharge from the urethra being diminished as that from the bladder becomes more copious and the other symptoms
more distressing. On the other hand, the chronic forms of muco-cystitis, especially when they go on to ulceration, perforation, &c., induce disease of the kidneys, most frequently of the left kidney (Raven, Richter, F. Frank, Coulson, &c.). In these latter cases a dull pain is felt in the loins, is increased by pressure, and is ushered in by chills, rigors, sickness at stomach, and an albuminaceous urine, which also contains large quantities of puriform matter, often tinged with blood.

71. With ulceration of the mucous coat, hypertrophy of the muscular coat, contraction and thickening of the parietes of the organ generally result. The bladder, owing to its irritability, is constantly contracting upon the urine poured into it; and spasm of the sphincter often causes a regurgitation into, or an obstruction of the ureters; which thus become distended and tortuous, and still further changes are thereby induced. "The mucous membrane, extending upwards along the ureters to the pelvis and the infundibula of the kidneys, becomes inflamed and rough, and pours out a quantity of pus. The glandular structure of the kidney undergoes from pressure slow absorption. The lower part of the ureters, on the contrary, increases in firmness to the exterior of the gland. Upon making a section of a kidney so diseased, we find that, although apparently of large size, it consists in great part of diluted tubes, and that the true vascular or secreting part is in smaller proportion than usual." (Op. cit. p. 144.)

72. The complications either of muco-cystitis or true cystitis are chiefly with diseases of adjoining parts, and arise from the extension of inflammatory action, either to these parts from the bladder, or from the latter to the former. Inflammation of the urethra, prostate gland, strictures of the urethra, calculus vesicae, hamorrhoids, colo-nitis or inflammatory dysentery, inflammations of the rectum and of the uterine organs, and kidneys, &c., may separately extend to, or excite inflammation of the bladder. On the other hand, this latter may involve the adjoining parts; it may extend from the former to the uterus, or to some of the convolutions of the intestines, or it may occasion peritonitis. This is not a frequent occurrence; but firm adhesions of one or other of these parts to the fundus of the bladder have been found on rare occasions, where, from the history of the cases, the bladder was the original seat of disease.

73. Inflammation may extend from the mucous coat of the bladder to the ureters, and along their course even to the kidneys; but this very frequent and important complication of urae-cystitis is most probably not often produced in this manner, but much more frequently by the occlusion of the ureters where they pass through the coats of the bladder, owing to the tunelled state of the inflamed parts at this situation. In this case the urine is secreted for awhile, but cannot pass into the bladder, owing to this condition of parts. Inordinate distention of the ureters, pelvis, and tubular structures is the consequence, and serious disease and disorganisation, not only of these parts, but also of the constitution, result.

74. The extension of inflammation of the bladder to the uterine organs is not infrequent; occasionally not merely adhesions between the serous surfaces, but also, particularly when cystitis is consequent upon, or is attended by retention of urine, retroversion or obliquities of the uterus, leucorrhoea, &c. The most frequent complication of cystitis is stone in the bladder, the inflammation being consequent upon, and generally occasioned by the solid concretion. The most frequent connection also for the development of uro-cystitis with gout and rheumatism, either as consequences of the displacement or metastasis of these, or as occurring from other causes, owing to the predisposition to urinary disease occasioned by them, should not be overlooked, when ascertaining the causes and the relations of cystitis, or when determining the indications and means of cure.

75. v. Appearances after Death.—These vary much in different cases, and are more generally the consequences than the states forming the early, or even the advanced, states of the disease.—I. After acute Moro-cystitis, the inner surface of the bladder is thick, rough, of a reddish-pink hue, from capillary dissection, with small ecchymoses, owing to exudation from the congested capillaries. The inflammation in most fatal cases is found to extend over the whole inner surface, although greatest in some parts, especially near the neck of the bladder. This thickening is sometimes found covering or attached to the mucous coat. This tume, in the most acute cases, may be detached from the muscular in parts, or even throughout, forming a greyish layer resembling a false membrane. In many instances the mucous coat has been destroyed by ulceration; sometimes, however, round ulcerated spots, the size of a sixpence, are found in different parts, with elevated edges and a red surface. Ulceration generally commences at or near to the neck of the bladder, and extends more or less to the fundus; but it sometimes begins in the latter, and advances to the former. In the most severe cases the muscular coat is involved in the inflammation, presenting gangrenous or disorganised spots. One or other of the kidneys is also generally diseased, the pelvis being dilated or ulcerated, containing pus, and the ureters also extending dilated and ulcerated at their vesical extremities.

76. B. In the slighter or early states of chronic muco-cystitis the mucous coat is found, in cases of death from other diseases consequent on the former, injected, discoloured, thickened and softened, and its follicles enlarged and inflated. It separates readily from the adjacent coat, is abraded in parts, and is even detached in spots by extravasations underneath. The parieties of the viscus are thickened and contracted, the muscular coat is greatly hypertrophied, and ulceration of the mucous coat penetrates to the muscular, or even further (§§ 68, 69). When the ulceration is extensive, the hypertrophied muscular fibres appear, and resemble the columnar carnations of the heart, presenting a purplish-red colour; the mucous coat between the columns thus formed being pale, soft, and swollen. Pouches, or sacs, generally exist, with dilated ureters, between these muscular columns, and are formed by the contractions of the bladder and of the abdominal muscles, in expelling the urine, forcing the mucous coat in places between the muscular fibres. These pouches are lined with a diseased mucous coat, which secretes an alkaline mucus, and are "sometimes the receptacles of a mortar-like matter, and finally of calculi, consisting generally..."
of phosphate of lime." As the disease proceeds in the mucous coat it extends to the ureters, to the pelvis, and to the tubular structure of the kidney; and pyelitis supervenes. Ultimately the ureters adjoin to the kidney affected becomes dilated, tortuous, its lining membrane inflamed, granulated, or ulcerated, or sometimes covered with lymph. The pelvis and infundibula are much dilated, whilst the secreting structure of the kidney is reduced to a thin layer.

77. There are states and other cases of muco-cystitis, patches of a red colour, more or less deep, or from a bright red to a violet shade, are found in the mucous coat; and small ulcerated specks or points, apparently affecting the mucous follicles, are seen in these patches. In the more chronic cases the ulcers are of considerable size. When numerous they are generally small. Sometimes an albuminous-puriform matter, adhering at points of the mucous surface, gives it an ulcerated aspect on a superficial view; and occasionally this surface appears elevated at numerous points, owing to an albuminous exudation in the superficial cortex. The whole internal surface of the bladder is but rarely affected, although the greater part generally is, in the form of large irregular patches. In protracted cases the mucous surface is thickened, and this change often extends to the ureters, and the connecting cellular tissue; whilst the blood-vessels are more numerous and more engorged than natural. With these appearances the bladder is generally contracted, and the mucous coat forms a number of large wrinkles or folds, is often softened, and is occasionally encrusted, or covered in parts with a calculus deposit. The prostatic gland is often enlarged in these cases, is somewhat diminished in consistence, and readily admits of being divided.

78. D. In true cystitis, especially when chronic, in addition to increased vascularity, more marked in some places than in others, the parietes of the bladder is much thickened, and more or less contracted; but the extent of these changes varies greatly, being generally greatest in cases of chronic cystitis arising from the presence of stone. In some cases the thickening is moderate, yet attended by a varicosce state of some of the veins of the viscus. Adhesions to adjoining parts of the fundus of the bladder, ulcerations, &c., are also seen in the circumstances and complications of the disease described above (§§ 63—69.).

79. vi. Diagnosis. — A. Muco-cystitis, when acute, may be mistaken for inflammation of all the coats of the bladder; but in the latter the desire to void the urine is much less frequent than in the former, and sometimes is not experienced until a large accumulation has taken place, and then it occurs in most severe paroxysms. The sense of scaling along the urethra felt in muco-cystitis is either slight, or absent when all the coats are inflamed. Occasionally the power to pass the urine is lost in this latter form of the disease; even when the desire is most urgent, and the act can be accomplished only after repeated efforts, or by surgical aid.

80. Many of the symptoms of acute muco-cystitis are experienced when stone is present in the bladder. But in cases where the pain is chiefly felt after the bladder has been emptied; whereas in acute muco-cystitis the pain is most intense when the bladder contains urine, and it subsides when the viscus is empty: in cases of stone, also, larger quantities of blood are passed than in muco-cystitis, and the urethra is seldom so irritable. (Coulson.)

81. B. Irritability of the bladder is to be distinguished from muco-cystitis, and true cystitis by the symptoms noticed above (§ 11.), and by the severity of the local affection, and of the constitutional disturbance. When, however, the irritability depends upon organic disease of the kidney, the diagnosis is more difficult. Mr. Courcy remarks, that the intense pain which attends inflammation and ulceration of the mucous coat of the bladder soon exhausts the patient, whilst in irritable bladder from diseased kidney there is sometimes, but not always, pain in voiding the urine; that the frequency of micturition is the most distressing symptom; and that, even when pain exists, it is never so severe as to wear the patient out, but may be, and often is, endured for years.

82. C. The chronic states of muco-cystitis are readily recognised. When mucus is passed in the urine in small or moderate quantity it may be the subject of no complaint, but when in larger quantity it is a symptom of some disease of the bladder, or of the prostatic fluid, which accompanies the evacuation of the faces or of the urine in some persons; but semen differs from mucus in its colour, in its property of liquefying on cooling, in its insolubility in water when recent and thick, and its solubility when liquid, and in the radiating crystals which it produces after evaporation. The prostatic fluid may be distinguished by its remarkable transparency, by its stringy and slimy properties, and by its retention of these conditions until it is dried. The prostatic secretion is often mistaken for the seminal in cases where it is discharged, both being passed immediately after the bowels and the bladder are evacuated; but the prostatic fluid is passed much more frequently than the seminal, which is thus voided much more rarely than is often believed to be the case. Chylous urine is different from the urine voided in muco-cystitis, in being of a uniformly white, watery hue, and the sediment formed by standing readily mixes with the urine on shaking; whereas the urine in this form of cystitis is at first turbid, and on standing the sediment becomes viscous, ropgy, flocculent, or muco-puriform, or even purulent, and it has the appearances already noticed. (§§ 47—49.)

83. vii. The Prognosis depends much upon the age, constitution, diathesis, and habits of the patient, and on the exact seat, severity, and duration of the disease. It may even still more depend upon the consecutive lesions already produced, and upon the presence or absence of complications. If the disease be primary and uncomplicated, and the patient young or middle-aged, and of a sound constitution, or has not previously been subject to disease of the urinary organs, the prognosis is favourable; but, on the contrary, if be aged, cachectic, has been subject to previous disease of the urinary organs, to stricture, or to any of the complications mentioned above (§ 70, et seq.), especially to disease of the kidneys, and still more particularly to this latter, occurring consecutively upon chronic muco-cystitis, the prognosis is unfavourable. In some the pain is chiefly felt in the subacute and chronic, if the pain continue, notwithstanding a judicious practice; if the micturition be still frequent; if the urine be
URINARY BLADDER—CAUSES OF CYSTITIS.

84. Causes of Cystitis.—A. The several forms of cystitis are most frequently met with in persons advanced in age, and in adults—particularly in the former. MM. LeSavie and Boisseau have, however, seen them in children between two or three years of age, and I have met with them as early as four and five years; but instances at this age are very rare, unless when accompanied with calculi in the bladder, or after injuries and operations. Cystitis frequently occurs in cold and humid climates, especially that form of it which is limited to the mucous coat; and it is common in persons addicted to fermented or spirituous liquors. Sedentary habits and occupations also predispose to it, especially in aged persons who are either confined to a sitting posture or to bed. An habitual neglect of immediately attending to the first desire of voiding the urine is a usual predisposing as well as exciting cause; the retention of this excretion occasioning irritation of the mucous surface and over-distension and diminution of contractility of the muscular coat. Females are less subject than males to muco-cystitis; but they appear quite as liable to the acute form of true cystitis, while they are less frequently affected with its chronic state, and to the complication of the disease with calculi and with disease of the kidneys. This partial immunity is owing to calculous concretions being less frequent and more easily removed in females; whilst diseases of the prostate and of the urethra are very frequent causes of the forms of cystitis in the male sex.

85. There are, perhaps, few causes which more frequently predispose to inflammations of the bladder than long-neglected disorder of the digestive organs, and especially to those states of cystitis which are complicated with calculous formations. There also seems to be a predisposition constitutionally inherent in some persons to diseases of the urinary organs, and consequently of the bladder, and especially in those of a gouty diathesis. Indeed, both the gouty and calculous diaetheses often originate in the same sources, namely in different vital enemies, with long-continued disorder of the digestive functions connected with an excessive use of animal food relatively to the amount of exercise in the open air. The connection of the former state of the system with disease of the bladder is very evident, and the incidence of the latter is decided. On the other hand, if each other in respect both of their common sources and of their exciting causes, are satisfactory proofs of predisposition independently of the evidence furnished by experience of the frequency of cystitis in gouty habits. Persons of a scrofulous diathesis, or who have been addicted to venereal excesses or to the habitual use of strong drinks, and of those who have been indulging in excessive dishes, to much animal food, and to sedentary occupations, are generally disposed to cystitis.

86. B. The most frequent exciting causes are, too long retention of the urine, exposure to cold and moisture, sitting on damp couches, sofas, or seats, or on cold stones, or on the ground; damp clothes on the lower extremities; damp feet; cold drinks whilst the body is perspiring; the abuse of diuretic and lithotriptic medicines; the excessive use of common gin; the inauspicious exhibition of emmenagogues; the internal use of cantharidines or turpentine in too large or too frequent doses; the abuse of aphrodisiacs; the introduction of a catheter or sound, especially by unskilled hands; irritating or improper injections thrown into the bladder; the irritation caused by calculi or by morbid states of the urine; external injuries, or blows on the hypogastrum, especially when the bladder is full; colitis when the viscera is distended with urine; hemorrhoids; catarrh, and the scrotal pedum, to which some persons are subject; the inauspicious suppression, without suitable internal treatment, of cutaneous eruptions, or healing of external sores or ulcers; the re-epithelialization of the bladder, or it may arise from the irritation of a calculus in that part of the ureter which passes between the coats of the bladder. It may also supervene in the progress of fevers, particularly of those characterized by stupor, coma, or delirium, or by congestion of the spinal chord, owing to the accumulation of urine of a highly irritating property; the local affection failing to excite the sensibility of the patient in these states, or the attention of the physician. The frequency and importance of this complication in fevers and in diseases of the brain and spinal chord should attract attention to it on every occasion, and on every ground.

87. Aubert, Carrel, and Chopart have recorded some cases in which large quantities of cantharidines had been taken as a cure for agues, and had occasioned cystitis of uncommon severity and fatal issue. The same result has followed the use of this substance as an aphrodisiac. Cystitis may also be the extension of inflammation from the pelvis of the kidneys to the bladder, or it may arise from the irritation of a calculus in that part of the ureter which passes between the coats of the bladder. It may also supervene in the progress of fevers and in diseases of the brain and spinal chord should attract attention to it on every occasion.
feet, especially when much water is in the bladder and a predisposition to inflammation of it exists, are occasionally causes of the disease. It may be remarked that a demulcent will in some persons more certainly produce its effects than the concurrent operation of several causes where little or no predisposition to the disease exists.

89. ix. Treatment.—A. Of Acute Muco-Cystitis.—The antiphlogistic regimen and treatment are required in all their details in this form of the disease. General and local bleeding should be prescribed, and even repeated, according to the age, habit of body, and constitution of the patient. Cupping over the sacrum, or leeches applied above the pubes or on the perineum, and repeated when circumstances indicate the propriety of the measure, are requisite; and in the milder cases, and in the less robust subjects, the local may supersede general bleeding. In some cases, especially when the symptoms indicate congestion or torpor of the abdominal viscera, or accumulations of sordes in the prima vesica, an enemiac will be given with benefit. After its operation has been freely performed the patient may be kept sufficiently moved by means of cooling aperients, as the infusion of senna with magpie, the neutral salts, or the carbonate of magnesia and sulphur, &c. Bleeding ought not to be carried too far, especially in the inhabitants of large towns, and in the aged, cachectic, or delicate. Nor should those purgatives which are liable to irritate the rectum or colon be employed; but the bowels ought to be kept regularly open. A warm general bath, or hip bath, is always of service, and should be resorted to as early in the disease as possible after the above means have been employed, and should be repeated as often as the state of the patient will admit. When the bowels have been evacuated, opiates, and demulcents or emollients are required, both to support the patient, and to allay the local irritation. These may be variously combined and exhibited, and may be conjoined with the alkaline carbonates. Morphia, or the preparations of opium, may be used, according to the medicines intended to be given along with either of them or at the same time. I have generally preferred the soap and opium pill, conjoined with an equal quantity of Castile soap. If these fail or lose their effect, emollient enemata should be administered, with either the syrup of poppies or compound tincture of camphor added tothem. When these prove insufficient to allay the local irritation, opiate suppositories may be resorted to, and a belladonna plaster be applied above the pubes, or over the perineum, or a suppository containing some extract of belladonna may be tried. The state of the urine must be daily tested, and, as long as it continues acid, the carbonates of the fixed alkalis may be given, in demulcent vehicles, with such other medicines as the particularities of the case may suggest. As the disease lapses into a subacute or chronic state, warm, or hip-bath, opiates with soap or alkalis, the infusion of pareira or of dioza, the preparations of cubebes, small doses of copiba or of the other balsams, and the infusion or tincture of hops, may be severely prescribed.

The acute form of muco-cystitis will be proscribed or pass into the subacute, and ultimately into the chronic form, if the regimen and diet of the patient be not duly regulated. All spirited, vinous, and malt liquors should be relinquished, as well as acidulated or sweetened drinks or fluids. The food ought to be farinaceous, demulcent, and vegetable, and prepared in as bland a form as possible. The drink should consists entirely of hoised-tea, barley-water, or toast-water, gum-water, or marshmallow tea, taken in moderate quantities.

91. In severe or obstinate cases some practitioners have recommended the injection of oil and opium into the bladder by means of a gauze catheter. As to this treatment, Mr. Coulson has very justly remarked, that the pain and irritation caused by the introduction of any instrument along the urethra are so severe, as to deter him from resorting to this treatment; for, unless there be retention of urine, the use of the catheter, sounds, and bougies should be avoided.

92. B. Treatment of Chronic Muco-Cystitis.—This form of the disease is often complicated with stricture of the urethra, or with disease of the prostate or kidneys; and it often also is consequent upon the acute form of the disease, owing either to neglect or to the administration of opium. In all cases, the treatment of this form of muco-cystitis is difficult, and more especially when it is complicated, and in the aged and cachectic. When the disease is simple, or consists chiefly of an abundant secretion of mucus (cystorrhoea), the decoction of pareira, or the infusion of cubbes, with opium or morphia, or with the dilute phosphoric, nitric, or nitro-muriatic acids, and the decoction or extract of uva ursi, are generally of service; but, where there are also much irritation and pain of the bladder, opiates given by the mouth, or in enemata are most requisite, and should be conjoined with every other method of cure. Sir A. Cooper recommends the balsam of copiba, in doses of eight or ten drops three daily, with musilage, sweet spirits of nitre, and camphor mixture. Mr. Coulson advises small doses of copiba, or of the essential oil of cubebes with hyoscynam, either to be given alone, or with the infusion of cubebes, or with the decoction of pareira. He adds, however, that both copiba and cubebes should be given with care; for, after the protracted use of these remedies, an aggravation of the disease may result. He frequently, therefore, gives the compound tincture of benzoin, in the dose of a tea-spoonful, three times daily; and, when the urine is alkaline, and contains much mucus with the phosphates, an infusion of the dried Alchemilla arvensis (one ounce to a pint of boiling water), the dose being two ounces of the infusion three times in the day. The muriated tincture of iron, the ammoniated tincture of iron, the balsams, Chio turpentine, and other kinds of turpentine, uva ursi, with camphor and nitre, the sulphates of iron and of zinc, have also been severally employed in this state of the disease, and are generally of service when aided by opiates, and when the disease is chronic, the urine warm, and the bowels are duly regulated. Dupuyer is relied much upon turpentine when the mucous secretion was great; and I have had occasion to observe its good effects; but it should not be long continued, although it may be given at intervals, or alternately with other means.

93. Persons of a scrofulous diathesis, or those addicted to venereal excesses, or who have suffered from syphilitic affections, or who are subject
to hemorrhoids or to gout, are liable, when they are attacked, to an obstinate form of this disease. For these the treatment should have more or less reference to the state of constitution, whilst the local affection also obtains sufficient attention. The aged and cachectic also require to have their constitutional powers supported whilst the urinary disease receives requisite care. But in these latter persons palliation alone can be hoped for; and the prolongation of life, by means of a restorative or curative treatment, opiate, in a low animal and vegetable diet is often the whole amount of benefit that can be expected.

94. When chronic mucous-cystitis is associated with stricture of the urethra, or is produced by it, the treatment is extremely difficult. Mr. Coules remarks that "the pain and irritation along the urethra are often so great as to render the use of catheters and bougies impracticable; and, unless the state of the urethra improve, no material benefit can be expected from internal remedies." Under these circumstances, having calmed the pain and irritation by means of sedatives, he proceeds to the use of the above gum-elastic catheter; and, if the stricture be of long standing and very narrow, he commences with armed bougies, introducing them once in three or four days.

95. The frequency of this, as well as other forms of cystitis in the gouty, and even also in the rheumatic diathesis; and of the occurrence of the disease in connection with, or upon the disappearance of gout, suggests the propriety of modifying the treatment conformably with this connection. In these cases I have found the opium and soap pill, with the extract of colchicum, taken at bedtime, and a sufficient dose of magnesia and sulphur, or magnoesia and rhubarb, early in the morning, to prove of great service. One or other of the above means already mentioned, avoiding the acids, may also be given in the course of the day, as circumstances may indicate.

96. Other means, which more especially belong to the province of the surgeon, have been advised in the more severe and protracted cases of mucous-cystitis. Sir B. Brodie states that when the symptoms are at their greatest height the mildest injections (into the bladder), even those of tepid water, will do harm rather than good. They are especially to be avoided when the mucus deposited by the urine is highly tinged with blood. When, however, the symptoms are abated, the injection of tepid water, or decoction of poppies is, in many instances, productive of excellent effects." The fluid should be allowed to remain in the bladder about thirty or forty seconds, and not more than two ounces should be injected each time. Distension of the bladder by the injection so as to cause pain is injurious, and should be avoided. The operation may be repeated two or three times in twenty-four hours. When the symptoms have abated and assumed a still more chronic form, and the mucus is free from blood, then one minim of the strong, or ten minims of the diluted, nitric acid, to two ounces of distilled water, may be used as an injection; the proportion by quantity should be increased. Mr. Coules remarks, that the tenacious mucus produced in this state of the disease deposits phosphate of lime; and when phosphate of lime from this source co-exists, as it often does, with the triple phosphate in the urine, a compound salt is formed; and that in such cases a weak solution of nitric acid (beginning with one minim of strong acid, increasing the quantity to two, to two ounces of distilled water) injected into the bladder acts as a salutary stimulant. As to Lallemand's cauterisation of the mucous membrane of the bladder with solid nitrate of silver, in cases of chronic cystitis, and as to Davison's injections with balsam of copaiba and narcotics, I must refer the reader to the work of the author just mentioned, and to other surgical works.

97. It should not be overlooked that excessive mucous secretion from the surface of the bladder, if neglected, or treated too long with some of the more healing substances, which have been advised, may be followed by a chronic inflammation of all the coats of the bladder, and ultimately by a subacute or an acute form of the disease, which may destroy the patient. This result is most likely to occur when the diet and regimen so requisite to the use of the bougies or that summarily neglected. In the milder form of the disease, animal food, in very moderate quantity, may be taken. The diet should be chiefly farinaceous, but the white kinds of fish, boiled, may be allowed. In the severer states animal food should be still more sparingly taken. If, in these, the vital powers be much depressed, sufficient light nourishment may be given, and tonics with the auburn carbonates, opiates, &c., may be prescribed. Spirituous, vinous, and malt liquors should be strictly prohibited; and all irregularity of diet and regimen carefully avoided. When there is great debility dry sherry may be allowed, especially if acidity of the prana via be not experienced. In all cases the functions of the skin as well as of the bowels should be duly promoted.

98. C. Treatment of Acute Cystitis—of Acute inflammation of all the Coats of the Bladder (§ 56.).—It has been above (§ 55.) stated that the inflammation may affect one of the tissues of the bladder more than the others, or may implicate them all, chiefly through the medium of the connecting cellular tissue, and that a portion of the bladder may be thus affected, or the whole of the organ; that when the inflammation is seated in the neck of the bladder, the urine is retained by the utricle occasioned by it; and that when the parts through which the ureters pass into the bladder are chiefly affected, the swelling which results more or less obstructs the passage of the urine, and occasions dilatation of the vesicles, ureters, &c., by its accumulation in these parts and suppression of this excretion. The consequences of the retention on the one hand, and of the suppression on the other, are always most serious and should be prevented by a most active treatment as soon as the disease is made and always dangerous states are present. The former may be removed by surgical aid; the latter by prompt and judicious medical treatment. But in most cases the treatment should have reference to the cause of the disease and the diathesis of the patient. When they show as produced by cold in any form, then the phlogistic form may be inferred, and supputation may take place, especially in the phlogistic temperament and full habit
of body. When it is occasioned by spirituous liquors, aphrodisiacs, or the suppression of the genito-urinary discharge, although all the coats may be implicated, the mucous will generally be chiefly affected, and the suppression of urine less frequently result. If the disease occur in the gouty or rheumatic diathesis, or follow upon suppression or metastasis of either gout or rheumatism, all the coats may be affected, and neither the fundus nor its peritoneal covering escapes.

In all these circumstances the treatment should be prompt and decisive, and the quantity of urine retained in the bladder carefully watched, by examining the hypogastrum and the quantity excreted. If the patient be young, or robust, or plethoric, although advanced in life, venesection should be prescribed and even repeated; and be followed by the local depletions, which may be sufficient for the delicate or weak, by cupping on the perineum, or by leeches applied to the part or to the pubes. Hot baths; warm fomentations above the pubes or on the perineum; the removal of the urine by means of the catheter with moderate artifices, laxative, and anodyne injections; cooling saline aperients, preceded by calomel and opium when the febrile symptoms are severe and the biliary functions are impaired; and demulcents with diaphoretics—are the means of cure which may be safely resorted to in all the circumstances of the malady just noticed. If the disease be consequent upon gonorrhea, obstinate or mucilaginous demulcents, with small doses of camphor, nitrate of potash and hubnese, in addition to appropriate depletions, diaphoretics, aperients, &c., will generally remove the more urgent symptoms. If it be connected with gout or rheumatism, magnesia and sulphur in equal parts, either alone, or with demulcents, and small doses of colchicum, will be found very beneficial, by moderately promoting the abdominal secretions and the functions of the skin; this latter being too generally overlooked, especially in gouty affections. Under the above treatment the symptoms generally subside gradually; but if retention of urine be long neglected; or if the urine be suppressed, owing either to delay in adopting the above means, or the constitution of the patient and violence of the attack, delirium, coma, and death will generally result. It may be asked, what should be done in cases where the urine has become suppressed? I would answer, after the above means have been judiciously employed, that warm flannels, or stupe, moistened with spirits of turpentine, should be applied over the hypogastric region and perineum, and that emollient enemata, containing equal parts of this substance and castor oil, and one or more ounces of olive oil, be administered and repeated as they may be required, whilst diaphoretics should be assiduously continued.

— Chronic uro-cystitis is often consequent upon the acute, but it is often a consequence of the stricture of the urethra, of enlargement of the prostate, of stone in the bladder, of prostatic calculus, of the abuse of spirituous liquors, especially of common gin; of the use of cantharides, or of cubebes or copaiba; or protruded gout and rheumatism, especially the former; and of the retention of the urine in the bladder after the desire to pass it. The nature of the cause influences more or less the treatment to be adopted. In strong, young, or plethoric subjects, and especially when considerable pain is experienced, local depletions, followed by warm baths, the semicompound of fomentations, &c., is always required. In many cases the removal of the primary disease will be the first indication, especially in the case of strictures, and in every case the retentive indication the employment of means which act more or less directly on the bladder should also be adopted. In most instances the selection of these means should be guided by the state of the urine. If this be acid or scortaneous, the bicarbonate of the fixed alkalis with nitrate of potash and sweet spirits of nitre, in demulcent or emollient vehicles, will be generally of great service; and anodynes, such as the syrup of poppies, tincture of hemlock, compound tincture of camphor, tincture of hop, opiate suppositories, &c., will also be prescribed in many cases with advantage. The preparations of pareira brava, or of the disoma, or of uva ursi, may, in the more obstinate or chronic cases, be given with the above, or the decoctions or infusions of these latter may be the vehicles for the exhibition of the former. When the disease occurs in the gouty or rheumatic diathesis, or appears after the suppression of either of these diseases, then the extract, tincture, or wine of colchicum, in small doses, may be prescribed with the alkalis, and a small dose of opium or of morphia; and when the pulse presents much strength or hardness, the tincture of aconite, in the dose of one, two, or three drops, may be resorted to, although this latter is more appropriate in the more acute cases, and when the peritoneal covering of the viscus is implicated in the disease. The infusion of parsley-root is sometimes of service in chronic uro-cystitis, especially when made the vehicle for some of the medicines mentioned above. Mr. Coulson states that he has tried the infusion of wild carrot-seeds in this form of the disease with advantage, but that it is not thought of if there be any irritation of the mucous membrane; and he adds that, as in these cases the bladder is, by its own efforts, seldom completely emptied, a catheter should be introduced from time to time, and the patient be instructed to do this for himself. Unless this direction be strictly attended to, the patient will become worse, and serious consequences ensue.

102. E. When inflammation is extended to the peritoneal coat of the bladder, either from the internal coats, or from parts in the vicinity of, or in contact with the peritoneum, the symptoms may
URINARY BLADDER—MALIGNANT AND ORGANIC DISEASES OF.

then be very acute, and become chronic from neglect or injudicious treatment. This form of the disease most frequent in females, especially after parturition or in some period of the pu-

eral state, and is generally contingent upon the occurrences which sometimes take place during this state. In some cases it is strictly a partial peritonitis, confined chiefly to the pelvic perito-

neum, but the symptoms in general, being distinctive of its nature and seat. (See Art. Peritoneum, inflammation of, § 76.) The seat of pain, tenderness, and tension, the rapidity of the pulse, the position of the patient, the expres-

sion of the countenance, &c., indicate the nature of the disease, which may be limited to the pelvic peritoneum, especially when coagulable lymph is thrown out, which forms adhesions between the opposite surfaces, and prevents the extension of the malady. In unhealthy constitutions, and in females in the puerperal state, the inflammation, instead of being thus limited, generally extends over the peritoneum, in which coagulable lymph, a serous fluid, of varied appearances, is thrown out, and the morbid action, commencing in the hypogastric region, extends through the abdomen, which becomes tender and tympanitic. The pulse is so rapid as hardly to be counted; hiccups supervene, and the disease presents the course and termination described in the article Peritoneum (§§ 19—36.) In these cases the treatment is the same as I have advised in that article (§§ 137—159. et seq.).

103. In rare instances an abscess forms below the peritoneum, between the bladder and the sym-

physis pubis, or some other adjoining part, as in a case related by Dr. Elliotson. Sometimes also a pseudo-abscess is seated within the pouch of the peritoneum, between the posterior wall of the bladder and the rectum. Lymph, in these cases, agglutinates some folds of the intestines, or the sigmoid flexure of the colon and the fundus of the bladder, and pus collects in the pouch formed by these parts. The contents of this pseudo-

abscess may be absorbed, if in small quantity, old adhesions alone remaining; or they may find their way into the peritoneal cavity, and occasion general peritonitis; the cases of this nature are mentioned by Mr. Coulson, and they have been seen by myself, but only in females and as consequences of pelvic peritonitis after parturition (see Art. Peritoneum, § 76. et seq.) and Puerperal Diseases (§ 221. et seq.).

104. V. MALIGNANT AND ORGANIC FORMATIONS are sometimes found in or attached to the pari-

etes of the urinary bladder. A.—Tubercles are occasionally deposited in the parities of this viscus, generally either under the peritoneal coat, at the fundus, and in the mucous membrane, near the urethra. In this latter situation the small gran-

ular deposits pass rapidly to ulceration. Tubercle of the vesical mucous membrane is, according to Borkovsky, rare, and is not always formed in connection with tubercular affections of the uri-

nary and sexual organs. Tubercle on the exterior of the bladder is generally seen associated with tuberculous affections in the female sexual organs, Mr. Coulson re-

marks, that the morbid deposit may be so great as to glue together the different organs, and thus in-

terfere with the free action of the detrusor urinae; but this can only occur when the tubercular cachexia is inordinately developed. The most frequent appearance of tubercle in connection with the bladder lies, especially after parturition, that part of the membrane covering the bladder partaking in the general alteration, the deposit being commonly in small distinct masses, the membrane being spotted, dark-coloured, or rugous, or otherwise altered. (See Peritoneum, § 41. et seq.)

105. B. A polyposic effusion from the in-

ternal surface of the bladder is very rarely ob-

served. Dr. Baxlie saw only one example of it, and that filled up the greater part of the cavity of the viscous. An instance of it occurred to Mr. Crosse, of Norwich, in a child. Other cases of polyposyc vesicse have been recorded by Mr. War-

ner and others, but they require no particular notice. The very interesting and instructive case published by the late Mr. Crosse will be found in Mr. Coulson's work.

106. C. Malignant formations in the bladder are not very rare. The worst form is that de-

scribed by Mr. Travers and others as the ma-

lignant medullary fungus, which arises from the sub-mucus ti-sue, and projects into the cavity of the vesicus as a soft, vascular, and emulsi-

flower-like mass, which bleeds upon the slightest touch. Mr. Travers states that it springs from "the mucous coat of the bladder, and resembles that of the nares and uterus, breaking, bleeding, and re-

producing as quickly as it is displaced. It is of very extensive attachment, and gradually reduces the cavity to very small dimensions. Portions of fungus and coagula of blood become plugged in the urethra, and form firm pellets, so as to produce retention of urine. It is a very painful disease. It keeps the patient in constant anxiety to void urine, which is more or less tinged with blood, and frequently he passes blood alone. He dies hectic and wasted." Mr. Coulson states that this malignant fungus is generally first developed near the neck of the bladder, the trigon, or the posterior surface; and that cases occur in which the vegetations fill a diverticulum or sacculus, where they form a tumour which may cause re-

ten tion of urine by its pressure. These tumours vary in size, some cases of this nature are mentioned by Mr. Coulson, and they have been seen by myself, but only in females and as consequences of pelvic peritonitis after parturition (see Art. Peritoneum, § 76. et seq.) and Puerperal Diseases (§ 221. et seq.).

107. A. The symptoms of malignant tumours of the bladder frequently resemble those of stone. Warner states that the first sign of this disease is a discharge of urine, or in any other cause than the cancerous diathesis, hereditary or acquired. (See Art. Cancer, § 23. et seq.)

107. a. The symptoms of malignant tumours of the bladder frequently resemble those of stone. Warner states that the first sign of this disease is a discharge of urine, or in any other cause than the cancerous diathesis, hereditary or acquired. (See Art. Cancer, § 23. et seq.)
to pass urine is one of the most common symptoms, accompanied with suppurative irritation of the rectum and inclination to stool. When blood passes from the bladder, after the introduction of a sound or catheter, or after the flow of urine has terminated or very nearly terminated, there is much reason to infer that it proceeds to the coats of the bladder; and when this occurs, in connection with the serous, muscular, and especially with the sense of the existence of a body or substance in the bladder, felt either by the patient or the operator when a sound is introduced, the existence of a malignant tumour, fungus, or polypus may be inferred. Ultimately, in these cases, consecutive disease and disorganization of the kidneys, with more or less marked disorder of the stomach and bowels, and exhaustion of the powers of life, is followed by a fatal issue. I may refer the reader to Mr. Corton's work for some instructive cases and post mortem appearances of this disease.

108. Disease of a disorganising nature may extend to the bladder from malignant disease of the rectum in men, or of the womb in females; and by means of ulceration a communication may be established between the rectum and the bladder, or between the bladder and vagina. Mr. Taveras, however, doubts whether the ulceration of the bladder in these cases be truly cancerous. In this doubt Mr. Coulson appears to partake. I have seen a few cases of extension of malignant disease from the neck of the uterus to the bladder, but in most of these have had reason to infer that the disease in the latter part took of the same character as that of the former.

109. b. The treatment of malignant disease of the urinary bladder is chiefly palliative, by means of narcotics, sedatives, &c., administered by the mouth or enema or in suppositories, as advised when treating of Cancer, and of diseases of the Urethra, &c. In many of these cases the hemorhage from the bladder is so excessive that the means are required to arrest the discharge and to sustain the powers of life. For these the tincture of the sesquichloride of iron, the decoction of pcaura brasii, with nitric, or hydrochloric, or picric acid, or urine be alkali, the uva ursi, with the alkalis, if the urine be acid; the secale cornutum, spirits of turpentine, and other anti-hemorrhagics and astringents, the recumbent posture, &c., are the means chiefly to be employed in, conjuncted with opiums, &c.

110. VI. Abnormalities of the Bladder are sometimes observed, either alone or in connection with malformation of other parts of the urinary or sexual organs. They are generally congenital, and proceed from irregularities of fetal development. Numerous cases and various forms of irregularity of formation are on record, but as respects any treatment which may be adopted for them they concern the surgeon more than the physician, and sufficient reference may be made to them in the subjoined Bibliography.

111. Foreign bodies are often found in the bladder, having been introduced at some previous period from the rectum or some part of the intestinal canal, through a perforating ulcer or sinus formed between the bowel and bladder. In many instances, when a foreign body has been found in this viscus, it has become incrusted by the urinary deposits to a greater or less extent. This subject will be found more appropriately discussed in surgical works, where also rupture of the bladder, here or there, is the bladder, and wounds and injuries of the bladder are most ably treated by their respective authors.

URINE AND URINARY DEPOSITS—Pathological Relations of.

1199

URINE AND ITS DEPOSITS.—Classif. — General and Special Pathology, and Therapeutics.

1. The urine is one of the chief depurating secrections in the animal economy, and one which when interrupted or arrested rapidly terminates existence. This secretion in some form or other occurs in all animals, either by a distinct apparatus, or by a vicarious or associated function, in which latter form it also takes place even in the vegetable creation; and in all it is characterised as the excretory function of nitrogenous elements and compounds, variously associated with other substances. In the human subject and in the more perfect animals the conditions of the urine depend upon the states of the frame generally, upon the states of the urinary organs, and upon the food and drink of the individual. Hence these conditions are of the greatest importance to the pathologist, by enabling him to recognise, 1st, those states of the system with which they are severally connected; 2nd, those lesions, functional and structural, of the kidneys, of which they are often the effects; and 3rd, the influences produced by the food and drinks of the individual upon his system and urinary organs.

2. The urine is derived from the blood— is a depurating secretion performed by the kidneys from the blood as long as those organs are acted upon by the organic nervous influence distributed to them, aided by whatever share of influence may be transmitted to them or their ganglia by the spinal nerves. The urine being derived from the blood, and being one of the chief depurating secrections by which the blood is preserved in due order of function, it must be manifest that the phenomena connected with the urine and its secretion become important indications, not merely of the states of the blood itself, but also of the several sources by which the blood is altered or corrupted.

Since I have stated in the first part of this work, and then explained (in 1832), that the kidneys conveyed from the blood the fluids carried into the blood, and with these fluids the excreta materials, the ultimate results of animalization, and various other elements and substances resulting from indigestion and mal-assimilation, or otherwise absorbed into the circulating mass. As long as the kidneys are in health and elastic, their functions are to take all the excess of the fluid elements of the blood, and of various saline and nitrogenous materials, are prevented from accumulating in the blood; these functions being strictly deforming, as respects the purity or quality of the blood, and eliminating, or excreting, the fluids and excreta, whatever be their nature or effects; and this not only the quality but also the quantity of the circulating mass.

4. It is thus obvious that the urine consists chiefly of the fluids and of the fluid parts of the aliment taken into the stomach, and carried into the blood; and that it contains not only saline and other ingredients derived from the ingesta, and from the changes which the ingesta undergo, in the digestive canal, and in their passage into the blood, but also the effete nitrogenous materials resulting from the waste and absorption of the tissues, which are first conveyed into the blood by the absorbents and veins, and afterwards eliminated from the blood, with the fluids in excess, by the action of the kidneys.

5. Such being the source of the urine, it may be inferred that the quantity and condition of this excretion will depend upon a variety of circumstances which require the recognition of the pathologist in his investigations of disease,— upon the states of the digestive and assimilating functions; upon the states of the circulating organs and of the blood; upon the states of the urinary apparatus; and upon the states of the other depurating and eliminating functions— upon those of the skin, lungs, liver, and intestines. In recent times, and in recent writings, the conditions of the urine have received a due, if not an excessive, share of attention, especially from the chemical pathologists; yet these conditions have been insufficiently investigated in their relations to the other depurating functions, and especially to that of the skin, this particular function being either altogether overlooked, or very imperfectly inquired into. When treating of the Blood (see §§ 115—160) and when giving a succinct view of pathology under the head Disease (see §§ 94—104, and 163. et seq.), I there stated the same general facts; and those of the same kind, but more explicitly and fully than I have now done; and since then (published in 1832) the same views have received the approval of both, because they have been altogether adopted by more recent writers, although without acknowledgment of their long previous existence in the pages of this work. I may request those who may be curious in this matter to read what I have stated in the articles and in the sections just referred to, and to peruse the fundamental doctrines in Dr. Golding Bird’s work on “Urinary Deposits,” where the subject of urinary pathology has been very ably discussed, and which, as it stands, contains the views, but even the terms, first adopted by me have been followed and employed. I should not have referred to these principles of urinary pathology if it had not been necessary, by asserting my own priority in respect of them, to defend myself from the extravagant imputation of adopting the ideas of others.

6. b. The doctrines insisted upon in the early parts of this work respecting the depurating functions of the kidneys and of other organs have been much more recently carried out by Dr. G.
Urine and Urinary Deposits—Pathological Relations of.

Hence, as regards those of the kidneys, and in many places so conformably with these doctrines—although with too manifest a leaning to chemical pathology and neglect of a controlling vital influence—as to induce me to refer to his evidence on several topics, where I believe it to be accurate, or to support my own views. The fundamental point, however, is that very often as far as the kidney extends; but it is too limited, inasmuch as it is confined to the functions of the kidneys. He states that "it is, indeed, a general law, that any substance which has entered the circulating mass, and not been required for the nutrition of the body, nor forming a normal element of healthy blood, always escapes from the system by the kidneys, providing it exists in a state of complete solution. Hence these most important emunctories have the duty of removing any imperfectly assimilated elements of the food which had been absorbed while traversing the small intestines, and escaping the general circulation, as well as excerting the often noxious results of unhealthy digestion. To affect these most important conditions, it is essential that the substance to be removed should be soluble, or at least capable of being readily metamorphosed into a body soluble in the water of the urine, as nothing can be excreted from the kidneys, without breach of surface, unless in a state of solution. The third function performed by the kidneys, is their serving as outlets to evolve from the animal organism those elements of the disorganisation of tissues which cannot perform any ulterior process, nor be got rid of by the lungs or skin. The disorganisation of those tissues here alluded to is a necessary result of the conditions for the growth and repairation of the body."—"The old and effete atoms of the animal structure are not excreted in the form of dead tissue; but, becoming liquefied, they re-enter the circulation, their elements being re-arranged. One series of combinations thus produced, rich in nitrogen, is excreted by the kidneys, whilst those products which contain a preponderance of the inflamable elements, carbon, hydrogen, and sulphur, are called upon to perform, chiefly through the medium of the liver, an important office previous to their final elimination from the system. Thus the blood is not only the source of the elements derived from the food which serve for the nutrition of the body; it also serves, like a sewer, to receive the matter arising from the waste and liquification of the old and exhausted tissues." (p. 256.)

7. Now, all the ideas contained in this quotation will be found fully and explicitly stated, as referred to above (§§ 3—5.) and in other places, but more correctly and more conformably with pathological conditions, than in the above passage in the first volume of this work, published many years before the appearance of "Urinary Deposits." Besides, Dr. G. Brown has overlooked the functions of the skin in relation to those of the kidneys, and has not taken a correct view of those of the liver in connection with the functions of the lungs, whilst those of the follicular apparatus of the intestinal canal and of the skin, have been altogether neglected. Yet all these functions, as I have elsewhere shown (see the Articles Blood, Cries, Disease, and Excretions and Excreting Functions, &c.), are more or less intimately related to each other and to the depurating functions of the kidneys, and often evince, even in health, a vicarious increase when one or more of the others are impeded or diminished, and a marked diminution when they are augmented. It should also be re-collected, when estimating the source and nature of the functions of the kidneys and of other eliminating organs, that it is not only the materials mentioned in the above quotation, which are eliminated, but also a portion of those resulting from the waste of the red-globules and fibrin of the blood, and that the kidneys are not the only depurating organs, the functions of the skin, liver, bowels, &c., being generally more or less impaired or otherwise disordered in those diseases which evince the most remarkable alterations in the state of the urine, these functions, especially that of the skin, being too generally neglected by modern physicians, in favour of the popular attractions furnished by the functions of the kidneys.

8. It is obvious, from what I have stated now and in earlier parts of this work respecting the sources of the urine, that this deputing secretion will vary in quantity and sensible appearances and physical properties, and even be remarkably altered, by a variety of causes—1st, by the quantity and nature of the ingesta, alimentary and liquid; 2nd, by the imperfect and disordered products of digestion and mal-assimilation resulting from impaired vital power or simple or complicated ailments; 3rd, by the "metamorphosis and waste of the several tissues and of the blood—the removal of effete materials into and from the blood—during the healthy processes going on throughout the frame; 4th, by the waste and metamorphosis of the structures and of the blood, when accelerated by local or constitutional diseases; 5th, by the absorption of morbid secretions, and deposits or formations carried into the blood and partially, chiefly, or altogether eliminated by the kidneys and other emunctories; 6th, by the varying states of the other depurating functions—by the increase and diminution of one or more of these, diminishing, increasing, or altering more or less the functions of the kidneys.

9. Dr. Proctor considered that the elements were not confined to the albuminous proteins, but were ranged, during the processes of metamorphosis or waste, as to be converted into uric acid, or urine of ammonia, and that the atoms or elements not composing these bodies form certain ill-defined principles. The ulcerate changes which the gelatinous tissues undergo during destructive assimilation this very celebrated physician supposed to be intimately connected with their conversion into urea, and some saccharine principle, or its closely the lactic acid. Baron Liebig followed in the path pointed out and first trodden by Dr. Proctor, and has been in several matters supported by the researches of Melder, Taylor, H. Jones, and others. According to Liebig's theory, the elements of muscular tissue are carried into the circulation, combined with water and oxygen; the latter, by its union with the carbon of the effete tissue, supports the temperature of the body. On reaching the structure of the liver, 50 atoms of carbon, 1 of nitrogen, 45 of hydrogen, and 10 of oxygen, with an unasserted but considerable proportion of sulphur, are filtered off from the portal blood in the form of bile. The more highly nitrogenised elements of the metamorphosed or wasted tissues are separated by the
kidneys from the blood, chiefly in the form of urea and uric acid, whilst the carbonic acid, formed by the slow combustion of the carbon of the original atoms of muscle in the capillaries, is exhaled from the surfaces of the skin, and bronchi, and air-cells.

10. It is manifest that the atoms or elements of tissues, which have become worn out, or which have given place to new deposits in the course of nutrition, are carried into the circulating mass, where they undergo progressive changes under the influence of vitality, and are ultimately eliminated from the blood by the depurating organs. It has been supposed that the states in which the several materials are found on their elimination are such as may be altogether imputed to the action of the excreting organs; but it is more probable that the atoms or elements composing the materials removed from the structures, as well as those composing the blood, more especially the albumen, fibrin, red globules, and even the saline ingredients, undergo a succession of changes or modifications during their circulation through the body, until the greater or ultimate change is produced by the organs which discharge them from the economy. It is not, however, conformable to the laws of the human frame that each organ should perform so simple and definite a function as the chemical pathologists believe. The skin certainly excretes carbonic acid; but it also discharges other materials by means of its follicular apparatus; whilst the bowels, chiefly by the same or a similar apparatus, also excrete effete materials from the circulation; and, although the combinations which are found during their elimination may be viewed as chemical, they are the results of vital action in health, are more or less modified in disease, and are such as rapidly undergo further changes after their discharge, or after death, which changes are more decidedly chemical, and such as their individual elements chemically dispose them to assume.

11. In health, the urine presents certain conditions, a., especially as respects specific gravity, at different periods and in different circumstances. These have been distinguished into, first, the urine which is excreted shortly after drinking freely of fluids, the nature of the fluids modifying the appearances and odour of the secretion. This (the urine potus) is generally pale, and of a specific gravity varying from 1:003 to 1:010. Second, the urine secreted shortly after the digestion of a full meal (urina chylus), varying in physical characters with the nature of the food, and other circumstances, and presenting considerable density, its specific gravity varying from 1:020 to 1:030. Third, the urine passed after a night’s rest (urina sanguinis): this is of intermediate density, and varies from 1:015 to 1:025. In order to ascertain the specific gravity of the urine, in health or in disease, the portions passed before retiring to rest, and on rising in the morning, should be separately tested by the urinometer, and the average density of the two will be a near approach to accuracy. Dr. Prout assigned 1:020 as the average gravity of healthy urine. M. Bricquefer stated that it is 1:018 in men, and 1:017 in women. In both sexes being 1:017; and Dr. Routt that the average of 18 healthy cases gave a specific gravity of 1:021.

12. The specific gravity of the urine at different periods of the day varies in disease, as well as in health, although in a less marked degree, and in some diseases more than in others; but this part of the subject has not been sufficiently investigated, and it is moreover liable to many sources of fallacy, as emotions of the mind, articles of diet, the beverages or drinks employed, the medicines taken, &c., &c., all combine to render the results of observation uncertain. The nature, the stages, states, and course of disease, as of hysteria and other nervous disorders, febrile diseases, &c., also remarkably increase the difficulty.

13. The quantity of urine passed in the 24 hours, as well as its density and ingredients, varies much in health, but still more remarkably in disease. The quantity and quality are modified by temperature, by exercise, by the functions of the skin, &c., by modes of living, clothing, &c. Dr. Prout estimated the quantity at 30 to 40 ounces in the 24 hours. Dr. Routt found the average of 18 cases to be 35 ounces. M. Bricquefer considered the quantity to be 45 ounces in men and 37 in women, the general use of soups and weak subacid wines in France being productive of the increased discharge; but among the beer-drinkers of this country, the amount given by Drs. Prout and Routt would be found much below the average.

14. The quantity of the urine is, however, no measure of the depurating actions of the kidneys; for 20 ozs. of urine in the 24 hours may carry off as much solid matter as 40 ozs. at a different time or in a different person; for a density of the former amounting to 1:030 will furnish an equal quantity of those materials to those afforded by the latter at 1:015. Dr. Day has shown that the formula for calculating the solids contained in the urine, given by Dr. Christie is the most correct; and the following table calculated from it by Dr. G. Brum will show at a glance the quantity of fluid and of solids existing in 1000 grains of urine of different densities. The gramavimetric having shown the specific gravity, the proportion of solid matter is at once indicated by this table:—

15. By measuring the quantity of urine passed in a given time, the weight of solids excreted by the kidneys may readily be calculated, by the ratio of the foregoing and the following table, a pint of distilled water weighing 8750 grains. The following table is given by Dr. G. Bird:—
The latter, haemorrhage in some part of the urinary passages has occurred. In the former case the specific gravity is moderate, and heat produces no change; in the latter, heat and nitric acid occasion turbidity, and blood-discs are seen under the microscope. A brownish tint is caused by a concentrated or dense state of the urine, as in fevers, the specific gravity being high; or by obstruction to the discharge of bile in some part of the biliary apparatus, and the presence of some or all the elements of bile in the circulation; or by the existence of blood in a less degree or altered state, and shown by the tests just mentioned. Blood and bile may occasion a greenish-brown tint, the former when the urine is alkaline, the latter when the urine is very acid. A green-brown hue of the urine indicates excess of sulphur and the presence of cystine. It is unchanged by heat or nitric acid. It should not, however, be overlooked that numerous articles of diet and of medicine affect the appearance of the urine. Chlmaphyla, hematoxylin, indigo, rhubarb, senna, &c., produce this change in a marked degree.

19. The fluidity of the urine sometimes varies. It is more or less viscid, owing to the presence of mucus or pus, or both, especially when alkaline, and in the layer formed at the bottom of the vessel; and in a slight degree in diabetes mellitus, when the frothiness caused by agitation continues for some time. Although fluid whilst warm, it becomes in rare cases jellatinous on cooling, owing to the presence of self-coagulating albumen or fibrin. This state indicates severe organic disease of the kidneys. I have, however, met with it at advanced stages of pregnancy.

20. The chemical composition of the urine has engaged the attention of chemists and physiologists for many years; and even now the elements contained in this fluid, although nearly, if not altogether, ascertained, are still topics of controversy, as respects either the origin of certain of them, or the successive changes of which they may be the ultimate products. As to the general principle, that the urine is an excretion by which the blood is depurated from the effete materials carried into the circulation from the metamorphosis and waste of the tissues, &c., as stated above (§§ 3—20), the work (see Bloom, §§ 115—160), no doubt can now exist; but the successive changes which these elements or materials undergo during their absorption and passage from their origins and sources, during their circulation, and during their ultimate discharge, — from their origin to their elimination from the body,— have been long topics of research and discussion, especially by the chemical physiologists and pathologists of recent times, who have been more disposed to view them as altogether chemical, than as vital and as modified, and even more or less altered, by the states of vital power and vascular action. To the specialist in medicine the chemical doctrine presents itself in its most favourable aspect, as placing urinary pathology in an isolated yet scientific position. To the general or legitimate physician, the conditions of the urine, in all its phases, and in the successive changes from their origins to their ultimate results, are viewed as ever varying effects of the influence of vitality throughout the frame, as manifested by the functions of digestion, assimilation, nutrition, metamorphosis, waste, and depuration.

16. It may readily be calculated from these tables, that if 1000 grains of urine, of the specific gravity of 1.020, hold 466 grains of solid matter in solution (Table I.), a pint of the same specific gravity, weighing 89-25 grains (Table II.) will hold 415-9 grains solid matter; and that, if two pints and a half of urine be passed, 1039-72 grains will be discharged in the 24 hours. Dr. Golding Bird has calculated from Dr. Christie's formula a very useful table for showing the number of grains of solids in, and the weight of, a fluid ounce of urine, of every density, from 1-010 to 1-040.

17. By multiplying the number of ounces of urine passed in the 24 hours by the two last figures of the specific gravity, the quantity of solids excreted will be obtained. Thus if three pints, or 60 ounces be discharged in the 24 hours, and the density of the several specimens given an average of 1020, the 60 ounces multiplied by 20-79 would give a product of 1247 grains, the quantity of solids excreted in the 24 hours. Dr. G. Bird estimates the average amount of solids excreted by the kidneys of the healthy adult to be from 800 to 200 grains in the 24 hours; numerous circumstances connected with occupation, exercise, diet, regimen, &c., modifying the results.

18. The tints presented by the urine in different diseases are of great importance in respect both of diagnosis and of treatment. These tints vary with the degree of dilution and the nature of the ingredients from nearly colourless, to the usual pale amber colour, to deep brown. When very watery, urine presents a faint greenish tint, as in early infancy, and in hystcra and chlorosis. If bile or blood be present in the urine, a variety of colours, from red, brown, blackish-green, or apple-green are produced, the latter having sometimes indicative of cystine. A reddish tint may be caused by purpura or by blood; if by the former, congestion of the portal circulation, or disease of the liver or spleen, may be inferred; if by
all which are not only under the complete and constant dominion of life, but are also the necessary agencies of the continuance of life; this department of pathology being inseparable, in its philosophic as well as in its practical relations, from all others which comprise the whole range and circle of morbid actions.

21. The urine in health contains:—1st, certain organic products, namely, urea, uric acid, creatine, creatinine, colouring and odorous elements; these more especially result from the metamorphosis and waste of the tissues and of the blood, and are separated from the latter by the kidneys: also other ingredients, more particularly lactic and hippuric acid, developed during the process of assimilation, and accidental matters carried into the circulation;—2nd, inorganic products, being saline combinations, derived from the food, especially sulphates, phosphates, chloride of sodium, and soluble salts taken with the ingesta, and often decomposed in their passage through the blood; also saline substances generated chiefly from the processes of destructive metamorphosis and waste, and of depuration, as sulphates and phosphates;—3rd, matters derived from the urinary passages, being chiefly mucus, debris of epithelium, and a minute quantity of phosphate of lime present in mucus. M. Beccari gives the following as the average composition of urine in males and females, and the quantity discharged in the 24 hours:—

22. a. **Urea.**—This important excretion, composed of C₂, N₂, H₂, O₂, = 60, is the form in which a large quantity of nitrogen is eliminated from the body; 270 grams of urea being discharged by a healthy man in the 24 hours. This substance is the product of the destructive metamorphosis or waste of organised parts (§§ 9, 10); but it is so rapidly carried out of the blood by the kidneys as to admit of only minute quantities of it escaping by the skin, unless when the functions of the kidneys are interrupted, and then it is discharged both by the skin and by the intestines in greater quantities. The food has a remarkable influence upon the quantity of urea in the urine. Dr. Lehmann found the quantity of urea excreted by his kidneys whilst living on strictly animal food, and whilst restricted to vegetable diet, as follows:—

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>

<td>67</td>
<td>50</td>
<td></td>
</tr>
</tbody>
</table>

23. According to Lehmann the quantity of urea and of uric acid excreted in the 24 hours is very much influenced by age. The following are the results of his experiments, as to the amounts of these substances excreted in the 24 hours:—

**Urea.**

24. b. **Uric Acid.**—Uric or histic acid, composed of C₁₀, N₄, H₁₄, O₆, = 168, is excreted by the kidneys to the amount of 8-1 grams in the 24 hours. Dr. Pauter’s opinion, confirmed by Dr. B. Jones and Dr. G. Brand, is that the greatest portion of the uric acid always exists in the blood in combination with ammonia; for this acid requires 10,000 parts of water at 60°, for solution, whilst there does not exist quite 2500 times its weight. Urate of ammonia is soluble in 480 times its weight of water; and as it occurs in urinary deposits, it requires for solution 2769 parts of urine according to the researches of Dr. B. Jones, who has shown that the presence of a moderate quantity of saline matter increases its solubility. Dr. G. Brand states the following as the mode in which uric acid exists in healthy urine. "Uric acid, at the moment of its separation from the blood, comes in contact with the double phosphate of soda and ammonia, derived from the food, forms urate of ammonia, evolving phosphoric acid, which thus produces the natural acid reaction of urine. If the whole bulk of the urine be to the urate of ammonia formed, not less than about 2701 to 1, the secretion will, at the temperature of the air, remain clear, but if the bulk of fluid be less, an amorphous deposit of the urate will occur. On the other hand, if an excess of uric acid be separated by the kidneys, it will act on the phosphate of soda of the double salt, and hence, on cooling, the urine will deposit a crystalline sediment of acid sand, very probably mixed with amorphous urate of ammonia, the latter usually forming a layer above the crystals, which always sink to the bottom of the vessel." (Op. Cit. 84.)

25. Without referring to Lehmann’s views as to the physiological origin of uric acid, which are contradicted by the experiments of Lehmann, and merely stating that these views are not corroborated by any subsequent researches, I may give the results of the researches of this latter physician:—
Dr. Bruce Jones, who has investigated this and other subjects connected with the chemical pathology of the urine, with great scientific acumen, has shown the immediate influence of food on the quantity of uric acid contained in the urine, to be as follows:

<table>

Specific Gravity

Groats. Uric Acid.

In 1000 Grains of Urine—

| After animal food | 1027 | 1:022 |
| Before            | 1024 | 0:49  |
| After vegetable food | 1025 | 1:010 |
| Before            | 1024 | 0:49  |

From these and other researches and considerations, it may be inferred that uric acid is derived from the nitrogenised elements of the effete molecules of the tissues, and from the elements of food abounding in nitrogen, which are not assimilated into the healthy constituents of the blood; and probably from the latter source, in larger proportion; and thus these nitrogenised elements are excreted from the blood in the states of uric acid, of uric acid combined with ammonia, and of urea; the causes of the preponderance of either of these being not satisfactorily explained.

25. Lactic acid and lactate of ammonia were said by Belzélius to exist in the urine, but were denied by Liebig. That lactic acid exists in the blood, and is excreted by the skin in health, and more largely in some diseases, is admitted. It is, however, found in the urine of herbivorous animals; and it probably undergoes some change before it is excreted by the kidneys in the human subject. Dr. G. Bird considers that what was mistaken for lactic acid in urine, is really a mixture of creatine and creatinine, these substances being formed in which the nitrogenised elements of worn out structures, especially muscular tissues, are removed from the system. Dr. Paquot believed that several of the constituents of urine were derived from the destructive metamorphosis of distinct and separate tissues, and these substances appear to support his views.

27. a. Hippuric, or o-xylene acid, exists chiefly in the urine of herbivorous animals, and occasionally in that of man. Its quantity in health is not constant, probably owing to the nature of the food. It is, next to bile and purpursine, the richest in carbon of any of the products of vital chemistry, and hence its abundance in urine may depend upon the states of biliary secretion and of the respiratory functions, impairment of these increasing its excretion by the kidneys.

b. Butyric acid is sometimes found in the urine, and may be either referred to the butter used in food, or to the imperfect assimilation of some other matter. It is seen in the cretaceous deposit formed in diabetic urine. This acid may also be derived from protein compounds.

c. The colouring matter of urine has been differently accounted for by Simon, Prout, Heller, G. Bird, and Scheerer. The last-named physician attributed it to the destructive metamorphosis of waste of red-blood corpuscles. Dr. G. Bird investigated its nature and composition, gave it the name of purpursine, and viewed it as a principle of urine chiefly in disease; and as a result of impaired excretion of carbon by the lungs and liver, this element being, when existing in excess in the blood, partly eliminated by the kidneys in this form (§ 27, 28).

30. g. Sulphur extractive exists in urine, and is derived from the metamorphosis of albuminous and fibrinous tissues, which contain sulphur and traces of phosphorus. "Whilst the greater quantities of their protein elements are converted into creatine and its allies and urea, a small proportion containing the sulphur and phosphorus is eliminated by the kidneys in the form of this peculiar extractive matter." The taurine, a constituent of bile, may also be one of the sources of the sulphur extractive of the urine. The nature of the food may also contribute materially to the quantity of this constituent.

31. h. Ammonia exists in urine combined with uric acid, and probably with phosphoric acid and soda, forming the triple compound known as microcrystalline salt.

32. i. The fixed salts of urine are those which are left after the other ingredients are destroyed by a red heat. They amount to nearly 140 grains in the 24 hours, and consist of combinations of chlorine, sulphurous and phosphoric acids, with soda, lime, magnesia, and potass. Of these the combinations of chlorine and phosphoric acid are probably derived from the food. Dr. Bird considers that the phosphoric acid and soda in the urine exist in the state of the common rhombic phosphate unless it be combined with the phosphates of ammonia. The soluble phosphates far exceed in quantity the insoluble salts, and are derived directly from the food as well as from the albumen and other elements of the blood. The insoluble phosphates, forming part of the structure of the body, and derived from the blood during the process of nutrition, are conveyed back to the blood during the metamorphosis and waste of the structures, and are eliminated by the kidneys. "Some of the phosphoric acid of the urine is in all probability generated from the action of oxygen on many of the structures of the body, into the composition of which phosphorus largely enters, as the brain and nervous system generally. But the greatest part of the phosphoric acid is derived really formed from without; the phosphates of lime and magnesia abundance in milk and most varieties of vegetable food; whilst the basic alkaline phosphates exist in flesh, in wheaten flour, legumines seeds, as beans, peas," &c. The interesting researches of Dr. B. Jones have shown that the quantity of phosphates, in a given quantity of urine, begins some relation to the periods of taking food, and to the nature and composition of the food. He found the quantity of phosphatic salts to be much greater after a diet restricted to vegetable, than to animal food. The quantity of phosphates of lime and magnesia in the urine are considerably increased after the ingestion of soluble salts of these two earths. The alkaline phosphates are most abundant shortly after a meal composed
URINE AND URINARY DEPOSITS — Pathological Relations of.

33. k. The quantity of sulphuric acid in the urine is too great to be accounted for by its presence in the food as saline combinations; and sulphuric acid has been found in the urine whilst food quite free from sulphates has alone been taken. According to G. Birk and Müller, the origin of this acid is to be referred to the oxidation of the sulphur which exists with phosphorus in those tissues which contain albumen and livine. During the metamorphosis or waste of tissues, the oxidation of the sulphur occurs, and explains the presence of at least a portion of the sulphuric acid met with in the urine. The existence of more than twenty per cent, of sulphur in taurine—one of the products of the metamorphosis of bile—accounts for a portion of the sulphuric acid, by referring it to the oxidation of the bilirubin during the recrystallizations of bile in the economy. As a portion of sulphur is excreted from the body in a non-oxidised form, a part only of the sulphur not required for the purposes of the animal economy undergoes oxidation. Professor Ronalds found, in five specimens of urine of healthy persons, the proportions of sulphuric acid, and of the non-oxidised sulphur, existing in 1000 grains, to be as follows:—

| Percentage | 1-06 | 0-17 | 1-46 | 0-18 | 1-42 | 0-18 | 2-44 | 0-133 | 1-32 | 0-105 |

34. Dr. Bence Jones has shown, by his interesting researches connected with the subject, that the salts of this acid are increased in the urine by any kind of vegetable or animal food; that exercise does not appear to increase them, nor the administration of sulphuric acid, unless in large quantities; and that the ingestion of sulphur, or of the sulphates of soda or magnesia, always greatly augments the quantity of the sulphuric salts in the urine.

35. t. The chloride of solutum of the urine is obviously derived from the common salt taken with the food. Some of the saline constituents of the urine may be readily recognised by the crystalline forms they present when the urine is evaporated on a glass plate. M.M. Regnault, Bessey, and Burrai have shown that the chloride of sodium increases the excretion of nitrogen, as evinced by the augmentation of urea and the nitrogenised compounds in the urine. It may be inferred that common salt produces salutary effects:—1st, by furnishing hydrochloric acid to the stomach; 2nd, by furnishing soda to the bile; 3rd, by aiding the metamorphoses of the blood globules and of the tissues; and, 4th, by promoting the depuration of the blood. The absorption or diminution of chloride of sodium in the urine of patients with scurvy noticed by Reichenbacher was attributed to the alteration of diet during this disease. But Dr. Lionel Beale has established the following propositions, which show the insufficiency of this explanation:— 1st. Chloride of sodium is totally absent from the urine of pneumonic patients at the contraction of the period of convulsion. (p. 17). 2nd. The chloride reappears after the resolution of the inflammation. 3rd. The chloride exists in the blood in the largest quantity when most abundant in the urine, and rice veral. 4th. The chloride exists in very large quantity in the spuTa of pneumonic patients. 5th. There is reason to believe that the chlorides in pneumonia is determined towards the inflamed lungs, and is resorbed and removed on the resolution of the inflammation. (Transactions of Medical and Chirurgical Society, vol. xxxv. p. 374. &c.) I may, however, remark, that the quantity of chlorides in the expectation is increased beyond that existing in healthy pulmonary mucus, and is diminished in the urine, in acute bronchitis, in pleurisy, and in phthisis, although not so remarkably as in pneumonia.

36. III. The Formation of Urinary Deposits.*

* Clinical Examination of the Urine.—Dr. Golding Bird has given the following recommendations for ascertaining the state of the urine in disease, provided that it be an average specimen of that passed in the preceding twenty-four hours, or that resulting from the first micturition after a night's rest, unless the urine secreted at other times be required. A. Urine without deposit, or poured from the settle- ment. After ascertaining the alkalinity of the urines, the state of the urine by means of test-papers; a little of the urine should be heated in a metallic vessel or in a spirit-candle, or in a test-tube over a spirit-lamp; and if a deposit occurs, albumen or an excess of the earthy phosphates is present; the former, if a drop of nitric acid does not re-dissolve the deposit, the latter if it does. If the urine be very highly coloured, and be not rendered opaque by boiling, the colouring matters of bile, or purpurne, are present. To determine this, pour a thin layer of urine on the back of a white plate, and allow a few drops of nitric acid to fall in the centre, an immediate and rapid play of colours, from bluish green to red, will be observed; if bile; but no such change will be observed, if purpurne alone exists. Should the high-coloured urine alter in colour or transparency by heat, the presence of blood should be suspected. If the addition of nitric acid to deep-red urine, unaffected by heat, produces a brown deposit, an excess of uric acid exists. If a specimen of urine be pale, immerse the gravimeter, and if the specific gravity be below 1012, there is a considerable excess of water; but if above 1016, the presence of sugar, or a superabundance of urea, is indicated. To determine the existence either of these constituents, place a few drops of the urine in a watch-glass, add an equal quantity of nitric acid, and allow the glass to float in some cold water; crystals of nitrate of uric acid will appear on two or three minutes, if the latter exists in excess. Should this change not occur, the urine must be examined specially for sugar, which, it must be remembered, may exist in small quantities, without raising the specific gravity of the fluid. For this purpose, boil a small portion with an equal bulk of liquor parasse, in a test-tube, and the development of a brown colour will show the almost certain existence of sugar. An excess of colouring matter, rich in carbon, should always be sought after on account of its pathological importance.

"This is readily done, by boiling some urine in a tube, and, whilst hot, adding a few drops of hydrochloric acid. If an average proportion of the pigment exists, a faint red or blue colour will be produced; but if an excess is present, it will be indicated by the dark-red or scarlet colouring tint assumed by the mixture. Should the urine be alkaline, and a drop of nitric acid; if a white deposit occurs, albumen is present; if blood be evident, the deposit as above, if the addition of the acid, the urine has been converted into carbonate of ammonia." (pp. 16. 17.)

B. Examination of the sediment deposited. "If the deposit is flocculent, easily diffused on agitation, and scanty, not disappearing on the addition of nitric acid, it is chiefly made up of healthy mucus, epithelial debris, or occasionally, in women, of secretions from the vagina. Hemorrhoidal disease is the common cause seen, and apparently viewed, and a drop of nitric acid; if it wholly or partly dissolves, it is composed of mucus alone, if slightly affected, of mucus. If the deposit coagul-
3206 URINE AND URINARY DEPOSITS — PATHOLOGICAL RELATIONS OF

Et seq. — When the several constituents of the urine are in due relation to each other, the urine is clear, and of a pale amber colour. Its transparency is due largely to the metabolism on cooling by the gradual subsidence of a slight mucous cloud sometimes entangling a few microscopic crystals of uric acid; but when one or more of these constituents exist in real or comparative excess, or a new substance is super-added, the urine does not generally remain clear, but either immediately upon standing, or on cooling, becomes more or less turbid. When the urine, on cooling, becomes covered with a thin membrane-like scum, a pellicle is said to exist. When the substance causing opacity floats between the surface and the lower portions of the fluid, it is said to form a cloud. And when this fails towards the bottom of the containing vessel, the appearance was termed encrema. When a positive deposit collects at the bottom of the vessel, the term sediment, the hypostasis of the ancient, is commonly applied. The terms pellicle, cloud, and deposit or sediment are the commonly used names in describing the states of the urine. These appearances are generally not fully developed until the urine is cooled down to the temperature of the air. This is especially the case with those deposits which are soluble in warm water; as the urates, particularly those of uric acid, which compose the chief part of reddish and faintly-coloured amorphous sediments.

37. Urinary deposits, including all substances which disturb the transparency of urine by their presence, whether they subside to the bottom of

Like a creamy layer in the bottom of the vessel, the supernatant urine being coagulable by heat, it consists of pus. Urine sometimes appears opaque from the presence of a light flocculent matter diffused through it, presenting neither the tenacity of mucus, nor the dense opacity of pus. Although scarcely sufficient in quantity to interfere with the perfect fluidity of the urine, if a little be placed in a test-tube, and agitated with an equal bulk of liquid potassium, the mixture will often become a stiff, transparent jelly. This peculiar appearance is demonstrative of the presence of the exudation, or large organic globules formed under the influence of irritation, providing the urine does not coagulate by heat; for should it do so, the existence of minute quantities of pus may be suspected.

If the deposit is white, it may consist of urates of ammonia, phosphates, or cystine: the first disappears on heating the urine; the second, on the addition of a drop of dilute nitric acid; whilst the third dissolves in ammonia, and the urine generally evolves an aromatic odour, like the sweet-brier — less frequently being feebly. If the deposit be coloured, it may consist of red particles of blood, uric acid, or urate of ammonia stained with purpurea. If the first, the urine becomes opaque by heat; if the second, the deposit is in visible crystals; if the third, the deposit is amorphous, and dissolves on heating the fluid. Oxalate, and more rarely, a small quantity of bile, are often present, diffused through the urine, without forming a visible deposit; if these are suspected, a drop of the urine, examined microscopically, will detect the character of the crystals.

If the urine be opaque, like milk, allowing by repose a creamy layer to the surface; an emission of fat with albumen is probably present. Agitate some of the urine for half an hour, or even in a test-tube; and after resting a few minutes, a yellow chorial solution of fat will float on the surface of the urine, a tremulous coating of albumen generally forming beneath it.

Dr. G. Bird adds that much of the little time required for the investigation of this sketched may be saved, by remembering the following facts: — If the deposit be white and the urine acid, it in the great majority of cases contains urate of ammonia; but, should it not disappear by heat, it is phosphatic. If a deposit be of any colour inclining to yellow, brown, pink, or red, it is almost sure to be urate of ammonia, and visible crystals, in which case it consists of uric acid. (pp. 15–51.)
URINE & URINARY DEPOSITS — Pathological & Therapeutic Relations of.

always reddens litmus paper, and often contains an excess of urea, so as to crystallise when mixed with nitric acid. Its specific gravity is generally above 1.020, excepting in infants, in whom, deposits of uric acid are common, although the urine may be pale and of a much lower density. These deposits "appear as a yellow crystalline sand, whilst the supernatant urine is of low specific gravity, often 1.006, as pale as water, and contains very little urea." This circumstance arises from the form of alkaline phosphates, the presumed solvent for uric acid in the urine of infants. For the various microscopic characters of uric acid deposits which can only be satisfactorily shown by engraving, I must refer the reader to Dr. G. Bino's interesting work.

41. B. Diagnosis of deposits of urate of ammonia.—These vary in colour, from white, through every tint, to a pale fawn (the oftenest met with), brick-red, pink, or purple. All these deposits have certain characters in common. They never take place; they can be readily dissolved, and quickly disappear on the application of heat. The darker coloured deposits require a higher temperature for solution than the paler; and when the urine is scantly and concentrated, as in acute rheumatism, the addition of a little water may be required before they quite disappear. The addition of liquor amnii, or liquor potassae, quickly dissolves deposits of urate of ammonia, rendering the urine a little turbid from the precipitate of earthy phosphates. Deposits of urate of ammonia always contain small quantities of the urates of lime and soda, and often of magnesia and potash.

42. Urine depositing urate of ammonia presents several modifications: — 1st, a pale urine of low specific gravity (1012) with a nearly white deposit, which, instead of entirely falling, forms masses in the fluid, and appears as a mucus pus. The application of heat shows at once its real nature by causing its disappearance. 2nd. A pale amber-coloured urine, of a specific gravity about 1.018, which, on cooling, deposits a copious fawn-coloured substance resembling powdered bath-brick mixed in the water, but very readily disappearing on applying a gentle heat. This deposit occurs often, readily the small deposits disappear, and frequently attends a cold, obstructed perspiration, or slight indigestion. 3rd. A deeper-coloured urine, of a higher specific gravity (from 1022 to 1026), and deposits, on cooling, a reddish-brown sediment — the well-known brick-dust or laticious sediment. This variety generally is present during febrile excitement, and becomes turbid on the addition of a drop of nitric acid, "not from the coagulation of the albumen, but from the precipitation of uric acid in very minute microscopic rhomboidal crystals." 4th. Urine of a very deep colour, approaching to a copper, or purplish tint, or to purplish hue. This colour Dr. G. Bino attributes to the presence of purpurine. He adds that, whenever a deposit of urate of ammonia occurs in such urine, either spontaneously or by immersing it in a freezing mixture, it combines with the pink pigment, forming a kind of lake, and which is often so abundant as not to entirely disappear by heat, until the urine is diluted with water. This state of the urine is often observed in acute rheumatism, gout, in diseases of the liver and spleen, &c., and has been attributed to obstructed elimination of carbon.

43. ii. Pathological Relations of Uric Acid, and Urate of Ammonia.—Independently of the identity of changes common, although the substances in the urine, caused by the quantity and nature of the food, very important alterations of the proportions of these substances accompany and characterise various pathological conditions of the frame. Uric acid and its combinations have been attributed to various sources, viz., the waste or disintegration of the tissues, and nitrogenised food. But it appears to me that too large a share of these sources has been imputed to the former (which is more correctly the nutritive metamorphosis, and waste of the tissues), whilst the metamorphosis and waste of the globules, fibrine, and albumen of the blood, as contributing to the formation of these substances in the urine, have been overlooked. In disease, especially in acute diseases, as long as the kidneys are enabled to discharge their functions, an increase of uric acid and its combination appears; as the kidneys cease to discharge, and this increase is to be imputed chiefly to the waste of the tissues, and of the hamato-globuline, for little or no nitrogenised food is generally taken in these cases, but emaciation, and with this more or less of anaemia, supervene. The anaemia, which is often remarkable, especially in the advanced progress of these diseases, is often overlooked. In acute rheumatism, gout, fevers, diseases of the liver, spleen, &c., the elements and sources of uric acid and its compounds are abundantly supplied by the states of the blood to the kidneys; and uric acid, both pure and combined, is greatly in excess in the urine. M.M. Besquerel and L'Herretier found, in eleven cases of inflammatory fever, and twelve of continued fever, the uric acid more than double that in health.

44. That uric acid and its combinations may be formed to some extent in the blood, at least in some diseases, especially gout, rheumatism, erysipelas, &c., and eliminated by the kidneys, is rendered probable by the circumstance of urate of soda having been detected in the blood by Dr. Garrod. But the presence of this combination in the blood does not preclude the elaboration of a portion of the uric acid and its compounds, or the modification and metamorphosis of one or more of them, or their elements, by the kidneys.

45. In diseases of debility, especially in those characterised by depressed or exhausted organic nervous power, and by a poor or annihilated state of the circulation in its primary, chlorosis, disorders of irritation, &c., uric acid and its compounds are greatly reduced in the urine, unless the quantity of urine passed be remarkably diminished, and no deposits are formed.

46. The state of the periphrasitory function is too often overlooked by those who attend especially to the urine. Whenever the functions of the skin are impaired or interrupted, those of the kidneys are augmented; and the results are reversed when the periphrasitory actions are increased. But the increase or diminution of either does not
consist merely in the watery element, but also in the nitrogenised and other materials held in solution. This recuperative or vicarious function, and more especially the frequent want or imperfect discharge of the effete products of metabolism, are most intimately connected with the origin of many diseases, and are not the less productive of most dangerous results in the progress of others. I have always insisted, in my lectures (delivered from 1826 until 1842), upon the influence of an insufficiently depurated blood—of effete materials circulating in the blood—owing to impaired function of either the kidneys, the skin, or the intestinal mucous surface and follicles, or of two or all of these; or to an imperfect compensation of function of the others, when one is impaired or interrupted, in causing diseases not only of a serious and acute character, but also of a chronic and obstinate, although not dangerous kind. Most of the diseases of the skin, especially those which are most disposed to become chronic, are induced, or perpetuated, or both, not only by imperfect depuration of the skin and its appendages, but more especially and remarkably, also, by imperfect action of the kidneys, and of the intestinal mucous surface and follicles; the effete and nitrogenised elements and materials, and their combinations, retained and accumulating in the blood, irritating the cutaneous capillaries, and the capillaries of predisposed and sensitive surfaces and tissues. The crises of fevers and inflammatory diseases are merely the returning functions of depurating organs, and the free discharge by these emunctories of effete nitrogenous elements and materials and their compounds, chiefly by the kidneys, bowels, and skin. This doctrine has been fully elucidated in the Articles Blood, Crises, and Disease (published in 1832 and 1833), and has been applied to the illustration of the causes and phenomena of crises (See §§ 15 — 20.). Long after the publication of my views, Professor Liebig referred the products of elimination from the blood by the emunctories, and especially those discharged by the kidneys to chemical changes; but his explanations are opposed to clinical observation; whilst the researches of M. Becquerel (Séminaire des Urines, etc. 8vo., Paris, 1841) tend to confirm the opinion contained in the articles previously referred to.

47. (a). Excess of urine acid, or of its combinations with bases in the urine, the quantity of this fluid being natural, occurs in fevers, acute rheumatism, gout, erysipelas, inflammatory diseases, hepatic and cutaneous complaints, &c., chiefly from the waste and absorption of the tissues, and the metamorphosis of the elements and materials derived from these sources, and from the blood aided by oxygen conveyed into the circulation by the red globules. (b) A similar excess may also arise from an excessive indulgence in animal food, especially in highly nitrogenised flesh-meats, or from an indulgence in this kind of food beyond what is required for the nutrition of the several structures, or from a more moderate use of this food, due exercise, especially in the open air, being neglected. (c). Excess of those substances which are assimilated, and urine, although the supply of nitrogenised food is very moderate, owing to impaired digestive, assimilative, and nutritive function. (d). Excess may also occur in consequence of impaired digestive action of the skin and bowels; the kidneys discharging a more or less compensating function, and eliminating a portion or the whole of those elements and their combinations usually discharged by these other emunctories.

48. (b) Calculous Deposits of Uric Acid and Ureates.—An abundance of urine acid and of the urates in the urine may occur without producing much disturbance to the urinary or other functions. This is especially the case with urate of ammonia, which can hardly be ascribed to disorder, but rather to the healthy discharge of the depurating function of the kidneys. But, as Dr. G. Birk has justly remarked, "Uric acid or may be deposited in an insoluble form in the kidneys or bladder, and aggregating form a mass on which, by a kind of imperfect crystallization, great quantities of the acid or its salts may be deposited, giving rise to the formation of a calculus. Uric acid is of more serious importance than most other elements of calculous formations, not only from its constituting a large proportion of all urinary calculi, but as it is chiefly composed of other ingredients, the nuclei on which they are deposited, are, in the great majority of cases, composed of uric acid. Of 374 calculi contained in the Museum of Guy's Hospital, at the time I examined them, the nuclei are in 269 composed of uric acid or urate of ammonia. On account of its solubility, urate of ammonia is not a frequent component of entire calculi, although it often enters with other ingredients into their composition. Indeed, calculi wholly composed of this compound are almost peculiar to childhood; in Guy's Museum there are but eight concretions entirely consisting of this substance, although it constitutes the nucleus in eighteen. It is hence very probable that if ever by medical treatment we can succeed in overcoming a calculous diathesis, or dissolving a stone in the act of growth, it will be by means directed to the solution of the uric acid, or its combinations." (Op. cit. p. 154.)

49. (d) Treatment of Deposits of Uric Acid and Urate.—From the foregoing, it is apparent that excess of these materials in the urine, and the deposit of them, either in some part of the urinary apparatus, or after the urine is discharged, are contingent upon a variety of antecedent disorders or pathological conditions, which, in individual cases, require due recognition and appropriate means; and not upon those alone, but also, in different cases, or in different circumstances, upon an excessive or improper diet and regimen, or upon insufficient exercise. One of the most important and most generally prevalent of these conditions, more especially when these materials are deposited in large or unusual quantities, and still more particularly when they are deposited in any of the urinary organs, is depressed or exhausted organic nervous power, occasioning impaired digestion, assimilation, and nutrition. This condition suggests the employment of such means as experience has shown to be most efficacious in restoring the organic nervous power to its former energy, throughout the organs devoted to digestion, assimilation, and nutrition. This indication should be fulfilled, — 1st by medicinal treatment; 2nd, by suitable diet and regimen; and third, by exercise in the open air, and residence in a healthy locality.
50. *Medicinal treatment* comprises the several means of cure already recommended under the separate heads of *Indigestion*, *Gout*, *Pernicious*, &c.; but there are substances of which special reference may be made for removing and dissolving the deposits above noticed, and for counteracting the disposition to their formation. The medicines which may be employed in these cases are either restoratives and tonics, or are solvents of uric acid; and others may be so contrived that they are both remedial and preventive in this double capacity. The first of these consist chiefly of the tonic vegetable infusions and decoctions; the second of alkalies and alkaline salts; the former being generally made the vehicles for the exhibition of the latter;—more especially of the following, viz., the liquor potassii, Brandall's alkaline solution, the carbonate of potash and soda; the citrates, acetates, and tartrates of potash and soda; magnesia, and the citrate and carbonate of magnesia; the bichromates of potash and of soda; the phosphates of soda and of ammonia, and the benzene and citric acids. Certain Rhenish substances are likewise of use, especially the alkaline preparations of iron, the nitrate and oxide of silver or bismuth, and the sulphate and oxide of zinc, which may be given in various states of combination, and in the form of pill. It may be remarked respecting certain of the foregoing, that the preparations, especially the carbonates of the fixed alkalies, and the liquor potassie are often most beneficial conjoined with the iodide of potassium, and prescribed in a tonic bitter mixture; that the phosphate of soda may be taken freely in gruel, so as to act gently on the bowels; that magnesia will be most beneficial when given with sulphur, and so as to act upon the bowels, kidneys, and skin, which it will generally do when taken at night; and that the bicarbonates may be prescribed in stomachic infusions with salts of the vegetable acids. Benzoic acid was recommended by Mr. A. Une, to prevent the formation of uric acid. It may be given in doses of five to ten grains, thrice a day, with carbonate or phosphate of soda, or with the carbonate of ammonia, dissolved in boiling water. Citric acid was strongly recommended by Dr. Owen Rees for diseases, especially gout and rheumatism, in which uric acid and urates are concomitants; and whether it be given as an addition to the patient's drink, or in combination with the alkalies, it is often of great service. With magnesia, either in the form of citrate, or as recent lemon-juice or lemonade taken immediately after the magnesia, it is equally beneficial. 51. Most of the diseases, or slight states of disorder in which uric acid and the urates are deposited, are characterised by deficiency of the cutaneous excretion, and insufficient attention is directed to this function in many cases. The restoration of this excretion by means of the warm bath, or the vapour bath, followed by friction of the surface, by walking, or other active exercises in the open air, is a most important indication of cure where these deposits appear in the urine, both in preventing and in permanently removing the complaints in which they are the general concomitants.

52. h. *The mineral waters* which contain the alkalies, or sulphur, as those of Vichy, of Ems, or of Harrowgate, will also be resorted to with benefit. But whatever be the treatment, the quantity of flesh-meats used as food should be abridged, and farinaceous and vegetable substances, or the white kinds of fish, boiled, be partly substituted, more especially when exercise in the open air is not enjoyed, and when the functions of the skin are imperfectly performed.

53. c. *Uric Oxide—Xanthic Oxide—Xanthine, Pathological Relations of.*—This substance is a very rare ingredient of calculi, and it is known that it is formed by the decomposition of uric acid. The chemical constitution and the diagnosis of uric oxide are given by Dr. G. Bird, to whose work I may refer the reader. The character of urine depositing this substance is not known. The microscopic examination of a fragment of calculus consisting of uric oxide did not furnish any information, as respects a crystalline arrangement. The only recorded cases of the formation of this deposit occurred in children, and the calculus formed by it did not exceed a few grains in weight.

54. w. *Penicillium mealy.*—*Observations.*—Deposits of urate of ammonia coloured by this substance (§§ 39—42.) present tints varying from pale flesh-colour to the deepest carmine. "The presence of purpurine interferes with the ready solubility of the deposit with which it is combined on the application of heat, and free dilution with water is often required to aid its solution." Dr. G. Bird states that he has never seen purpurine colouring any other deposits except those of urate of ammonia, and hippuric acid when precipitated from concentrated urine by hydrochloric acid. Uric acid scarcely appears to have any affinity for it. It cannot be mistaken for blood, on microscopic examination, owing to the absence of blood-dises. The chemical composition of purpurine occurring in disease is not exactly known. Scurry states that that generated by the action of hydrochloric acid on urate consists of 62-51 of carbon, 5-79 of hydrogen, and 31-70 of nitrogen and oxygen. Urinary calculi sometimes present layers of urate of ammonia stained with purpurine. Dr. G. Bird remarks that all the deposits with which it is combined were, as far as he had observed, amorphous.

55. A. The Causes of the Disease of the Urinary Bladder.—When an excess of urate of ammonia is present, it falls to the bottom of the vessel as the urine cools, carrying with it a great part of the purpurine. "If this excess be not present, the urine simply presents a pink or purple colour, and on dissolving white and pure urate of ammonia in it by heat, it is precipitated on cooling, deeply coloured by the purpurine. The presence of the yellow extractive which yields purpurine can be readily discovered by the action of hydrochloric acid. On evaporating urine containing purpurine to the consistence of an extract, and digesting it in alcohol, a fine purple tincture is obtained—the intensity of the tint being rather heightened by acids and diminished by alkalies." The specific gravity of this high-coloured urine, when the colour is as deep as that of brandy, varies from 1·022 to 1·030.

56. B. The pathological Indications of an Excess of Purpurine are important. Dr. G. Bird remarks that the existence of purpurine in urine appears to be "invariably dependent upon some imperfection in the excretion of carbon by these..."
organs, whose special function it is to eliminate this element from the blood, as the liver and lungs, but especially the kidney. Hence it is almost always connected with some functional or structural mischief of the liver or spleen, or some other organ connected with the portal circulation. I have for many years ascribed the presence of this colouring substance in the urine to an increased waste of the red corpuscles of the blood, or of the haemato-globulin by the kidneys, and that the diseases in which it most remarkably occurs, as fevers, gout, acute rheumatism, phthisis, &c., are characterised not only by a rapid waste of the tissues, but also by the globules of the blood, giving rise in most cases to phthisical anaemia. There can be no doubt of the idea of disorder, torpor, &c., of the liver,—enlargements of the spleen, &c., being often associated with these and other diseases in which purpurae exists in the urine; but, in these, the waste of the blood-globules is not the less remarkable, this substance disappearing from the urine whilst it is diminished to the natural amount by restoration of vital power, by due oxygenation of the blood, and by improved digestion and assimilation.

57. v. Cystine, its Pathological Relations.—This substance does not exist in healthy urine, and rarely occurs in morbid urine. It is probably derived from the sulphur extractive of urine (§ 30). In its chemical composition it contains no less than 26 per cent. of sulphur. Cystine, Dr. G. Brad states, has been found in urinary sediments by very few observers, and it was not recognised in this form until a long period after its discovery in calcium by Dr. Willaston. In the rare cases in which it has been observed, it formed a nearly white or pale fawn-coloured pelverulent deposit, resembling pale urate of ammonia. The greatest proportion of cystine may be inferred to be merely diffused in the urine whilst in the bladder, as at the moment of discharge the urine is turbid, and immediately deposits a copious sediment. Dr. G. Brad states that, on applying heat to the urine, the deposit undergoes no change, and very slowly dissolves on the subsequent addition of hydrochloric or nitric acid. Pure cystine is soluble in the milder muriate, insoluble in the vegetable acids; with the former, it forms imperfect saline combinations, which leave by evaporation gummy masses or acicular crystals. It is readily soluble in ammonia and the fixed alkalies and their carbonates, but insoluble in carbonate of ammonia. Heated on platina foil it burns, evolving a peculiar disagreeable odour. Cystine may be distinguished from a deposit of urate of ammonia by not disappearing on heating the urine, and from the earthy phosphates by being soluble in very dilute hydrochloric or strong acetic acid. The best character of cystine is its readiness with some of the deposit with liquor ammonia being sufficient to dissolve it; and a few drops of the fluid, when allowed to evaporate spontaneously on a slip of glass, leaves six-sided tables of cystine. The ammonialaneous solution, when kept for some time in a white glass bottle, stains it black, fun the cystine is on the sulphur of the cystine with the lead in the glass.

58. v. The Character of Urine depositing Cystine is that of a pale yellow, or more of a honey-yellow than of an amber tint, presenting an appearance like diabetic urine. It is below the average specific gravity, is passed in larger quantity than usual, and is often neutral, seldom acid to litmus paper, and soon becomes alkaline. The colour of this urine is peculiar, and resembles that of sweetbriar. It is more rarely foetid, and when it is, the colour is generally greenish, or greenish yellow. "A certain portion of cystine exists in solution in this urine, as the addition of acetic acid always precipitates a small quantity." Even when this deposit has vanished, for some days together, crystals of cystine are then precipitated by acetic acid. Urea and uric acid are present in very small quantities, and in some instances the latter is nearly absent.

59. c. Calculi composed of cystine are generally pale yellow or fawn-coloured; but by long keeping they become greenish-grey, or a fine greenish-blue, probably owing to the action of light. The microscopic characters of cystine are very obvious. When it occurs as a deposit, it is always crystalline, never being amorphous. Among the crystals, a few regular six-sided lamellae are often seen, but the great mass is composed of a large number of superposed plates, so that the compound crystals thus produced appeared multiangular; but I must refer the reader to Dr. G. Brad's work, where this topic is well illustrated by wood-cuts.

60. c. The pathological Origin of Cystine is no further known than that it is inferred to proceed from the waste of the tissues, and probably also, of the haemato-globulin, or rather of some rearrangement of the normal course of this waste connected more especially with an excessive elimination of sulphur; every ounce of cystine containing more than two drachms of this element. Cystine may thus be formed from those elements of the tissues normally producing urea and uric acid with an excess of sulphur, owing probably to a deficiency of the process of oxidation in connection with impaired vital energy. That these latter states are evinced by the occurrence of cystine, or cystia-uria, in scrophulous, chlorotic, and anaemic subjects. The hereditary nature of this condition of the urine has been noticed by Dr. G. Brad, who states that in one family alone, several members were affected with cystinuria, and that one instance exists, in which it can be traced, with tolerable certainty, through three generations. In one case under the care of Mr. Lee, extensive disorganisation of the kidneys co-existed with a cystine calculus. Dr. Poate has seen fatty matter mixed with the urine in cystinuria, and suggests the probability of its connection with fatty liver. Dr. G. Brad thinks it not unlikely that the excretion of cystine may be a means, under certain circumstances, of compensating for deficient action of the liver, and the excretion of sulphur. The existence of cystine in the urine of chlorotic and debilitated females has been met with in several cases by Dr. Shearman of Rotham.

61. a. Indications of Cure.—Dr. Poate advises the prolonged use of nitro-hydrochloric acid, and found it of benefit in some cases. Having viewed the existence of cystine in the urine as a remission of debility in connection with imperfect oxidation of the blood-globules, I have in one case prescribed the chlorate of potash with tonic infusions. This view of the pathology of cystine is suggestive,
also of the employment of the tincture of the chloride of iron, of the iodide of iron, of chalybeate mineral waters, and of other tonics, for its removal, aided by a generous diet, by active exercise in the open air, and by due attention to the friction of the skin and nails. (See, also, the Treatment of Dilatity, of Cholorosis, and of Schorfula.)

62. VI. HIPPURIC ACID—HERRFIA. This acid is constantly present in the urine of the horse, and generally, also, in that of herbivorous animals. Lehmann found it in diabetic urine, and Leber detected it in healthy urine, although in minute quantity. As this substance never appears as a sediment until after the addition of a stronger acid, the diagnosis of it entirely depends upon the characters of the characters of the urine containing it. The urine containing an excess of hippuric acid is either very slightly acid, or neutral. It may be even alkaline. When this state of urine is caused by the ingestion of benzoic acid, it is then very acid. Its odour is common that of whey, and its specific gravity is below the healthy state, varying from 1-017 to 1-019. The deposit of the triple phosphate of magnesium is not infrequent in it. For the modes of detecting this acid, and for its microscopic characters, I must refer the reader to Dr. G. BIRD'S work.

63. 6. The pathological states causing this state of urine are not always obvious. In the lower animals it proceeds from vegetable food, it being constant in such as are not exercised, and replaced by benzoic acid in those that are worked. When in excess in human urine, it is ascribable to diet, thus it has been found after a prolonged milk diet, after an excessive use of apples, and in the urine of infants. This acid does not necessarily interfere with the production of uric acid, but generally it is attended by a deficiency of urea. It has been found in urine containing albumen. Dr. G. BIRD ascribes it to a diet deficient in nitrogen, or to the mal-assimilation of the carbon in the food, and infers that hippuric acid may be one of the agents by which the kidneys perform a vicarious function for the liver, in removing an excess of carbon from the system. In this respect, it may be viewed as an analogous result to the production of purpurgine and bile-pigment, each removing 63/93, 92/9, and 68/19 per cent. of carbon, respectively, from the system. It should be looked for in the urine when the functions of the liver, lungs, and skin are defective, when the food is deficient in nitrogen, and when the urine is copious, is slightly acid or neutral, and of low specific gravity.

64. VII. OXALATE OF LIME—OXALURIA.—Oxalate of lime often exists in the urine, and is frequently a constituent of calculous concretions. Its chemical and pathological relations have been ably investigated by Dr. G. BIRD, who contends for its frequent appearance as a crystalline deposit in the urine, in fine and well-defined octahedral crystals, and for the connection between the occurrence of this substance and the existence of a certain series of symptoms generally characterised by nervous irritability. He considers that the depressing influences, always present in densely populated cities, are more productive of this than the abuses of earthy phosphates; and that traces of oxalate of lime, in the minutest microscopic crystals, may be detected in the urine of persons free from any apparent disease. Hence he regards it as one of the common results of metamorphism of tissue. But this is very different from its presence in large crystals and in considerable quantities, these constituting a truly pathological condition.

65. a. For the Detection of oxalate of lime in the urine, I must refer to the work already quoted for the full details; generally, however, the existence of this substance may be ascertained by pouring off the upper six-sevenths of the water passed a few hours after a meal, having given it time to repose in a glass vessel. A portion of the remaining seventh may be warmed in a watch-glass to dissolve the urate of ammonia. Having removed the greater part of the fluid, and replaced it by distilled water, a white glistering powder like diamond dust now becomes visible; and this under the microscope will be found to consist of crystals of oxalate of lime in transparent octahedra, with sharply defined edges and angles. Dr. G. BIRD states that, out of a great number of specimens of urine containing the oxalate, it has scarcely ever seen the oxalate as a distinct deposit, but has remained diffused in the urine, even when present in so large a quantity that each drop, when placed under the microscope, was loaded with its crystals. But if any substance capable of being a nucleus were present, the oxalate would be deposited around it, although scarcely in cohering masses, and invariably colourless and beautifully transparent. The oxalate of lime, although absolutely insoluble in water, must be soluble in urine; for its lustrous crystalline form sufficiently indicates its previous solution, and it is not until after the urine has been voided several hours that the crystals of oxalate can be detected.

66. Occasionally some remarkable crystals of the oxalate resembling dumb-bells, or two kidneys with their concavities opposed, are met with, their surfaces being finely striated. But it is doubtful whether or not these are an oxalate of lime. Dr. G. BIRD considers them an oxalate of lime, a salt which differs from the oxalate in ultimate composition only in the presence of the elements of urea and absence of the constituents of water. Dr. BACON has investigated these crystals minutely, and has concluded that the dumb-bell crystals consist of a salt of lime containing either oxalic, oxaluric, or, perhaps, some other organic acid easily converted into oxalic acid; but the exact nature of the acid remains to be determined by future examination.

67. 6. The Characters of urine containing the oxalate of lime are those of a fine amber hue, sometimes darker than in health, in a few cases paler than natural, and of a lower specific gravity, the odour being generally natural or rarely aromatic like mignonette. Frequently a deposit of urate of ammonia, sometimes tinted pink by purpurine, falls during cooling. The specific gravity of oxalate urine varies extremely. Of 85 different specimens, Dr. G. BIRD found 9 in which it ranged from 1-009 to 1-015; in 27 from 1-016 to 1-020; in 23 from 1-021 to 1-025, and in 26 from 1-025 to 1-030. Generally the heaviest specimens contained the greatest of the oxalate. The quantity passed seldom exceeded 3000 cubic millimetres, even in instances of positive diuresis being rare. Irritability of bladder was sometimes complained of.
Acidity of the urine was well marked; even more so than in health, and always present. An increase in the quantity of urea was frequently found. Dr. Stalard observed in oxalic urine a great increase of the indeterminate organic matters (§ 211.), often as much as double the average proportion in twenty-four hours.

68. c. The Complications of oxalate of lime with other deposits are of some importance. Dr. G. Bird found the oxalate of lime unmixed with any other lime deposits in more than one half of the specimens of oxalic urine. "In a very few, crystals of uric acid were found from the first, mixed with the oxalate of oxalic acid; and in nearly all the successful cases, this acid appeared in the course of treatment, and ultimately replaced the oxalate altogether," at a period generally contemporary with convalescence.

"Much more rarely, prisms and stellar of the ammoniacal-magnesia phosphate were found mixed with the oxalate, and occasionally, replacing it in the course of treatment; and still less frequently, being the idea that oxaluria may be regarded as a form of what has been termed by Dr. Willis oxaluria, of which an excess of urea is the prevalent indication, part of the acid, or of its elements, having been converted into oxalic acid. It may be inquired, Whence are the elements which form oxalic acid? Are they derived from the metamorphic changes of the structure, as healthy urine and acid urine? Dr. G. Bird infers that they are. "Hence oxalate of lime must be regarded as one of the common results of metamorphosis of tissue" (p. cit. 210.). I am more disposed to agree with the opinion he has subsequently stated, viz. that, although it is probable that such may be the origin of oxaluria (in the waste of the tissues), yet, the quantity of oxalate of lime being greatest after a full meal, and often absent in the urine passed in the morning, frequently disappearing when the diet is regulated, and reappearing on the use of unwholesome food, it is equally probable that this salt is derived from the mal-assimilated elements of food. It is sufficiently obvious, from the nature of the complaints in which oxaluria occurs, that it is always the result of imperfect assimilation, or the formation of an impaired organic nervous power, the mal-assimilated or the non-assimilated elements forming the product in question, aided by oxidation, which product is rather eliminated, than formed, by the kidneys. However minute and laborious may be the researches of organic chemists in endeavouring to show the elementary combinations and the atomic affinities of these elements, in the production of urinary deposits, the vital endowment, and the states of function depending upon this endowment, more especially demand attention; the chemical constitution of the urine being generally only a sign, but an important one, of the state of this endowment, particularly as manifested by the organic nervous system.

71. e. The Symptoms accompanying the excretion of oxalate of lime have been minutely described by professors of observation between oxaluric acid and uricuric urine. From the symptoms present in cases where oxaluria is observed there can be no doubt that the primary cause of this state of urine must, as Dr. Provoit has shown, be imputed to an unhealthy condition of the digestive and assimilating functions. That the oxalic acid is formed from its elements, either in the digestive canal or in its course to and in the blood, must be inferred, since Dr. Garnett detected, beyond any doubt, octahedral crystals of oxalate of lime in the serum of blood from a patient affected with albuminuria. "It is difficult to explain the presence of so insoluble a salt in solution in the blood; but it is probable that the opinion of Dr. Sorenson, of Dorpat, may be correct. He has assumed that there exists in the animal economy a tendency to the formation of a soluble compound of oxalic acid, lime, and albumen, which, by its decomposition allows oxalate of lime to crystallize." Probably such a compound exists in the blood in disease; and when the acetic acid is added as in Dr. Garnett's process, the albumen is separated and the oxalate set free.

70. The chemical relation existing between uric acid, urea, and oxalic acid, and the readiness with which the former of these substances is converted into oxalic acid, etc., the identity of oxaluria may be regarded as a form of what has been termed by Dr. Willis oxaluria, of which an excess of urea is the prevalent indication, part of the acid, or of its elements, having been converted into oxalic acid. It may be inquired, Whence are the elements which form oxalic acid? Are they derived from the metamorphic changes of the structures, as healthy urine and acid urine? Dr. G. Bird infers that they are. "Hence oxalate of lime must be regarded as one of the common results of metamorphosis of tissue" (p. cit. 210.). I am more disposed to agree with the opinion he has subsequently stated, viz. that, although it is probable that such may be the origin of oxaluria (in the waste of the tissues), yet, the quantity of oxalate of lime being greatest after a full meal, and often absent in the urine passed in the morning, frequently disappearing when the diet is regulated, and reappearing on the use of unwholesome food, it is equally probable that this salt is derived from the mal-assimilated elements of food. It is sufficiently obvious, from the nature of the complaints in which oxaluria occurs, that it is always the result of imperfect assimilation, or the formation of an impaired organic nervous power, the mal-assimilated or the non-assimilated elements forming the product in question, aided by oxidation, which product is rather eliminated, than formed, by the kidneys. However minute and laborious may be the researches of organic chemists in endeavouring to show the elementary combinations and the atomic affinities of these elements, in the production of urinary deposits, the vital endowment, and the states of function depending upon this endowment, more especially demand attention; the chemical constitution of the urine being generally only a sign, but an important one, of the state of this endowment, particularly as manifested by the organic nervous system.
disorder or disease, to which, more especially, rational medication should be directed. Oxyuria is not a sign of one or even of two disorders merely, but of several, the chief morbid manifestations being depressed vital endowment of the digestive and excretory organs, with lowness of spirits, irritability or nervousness, hypochondriacal feelings, impaired nutrition, anaemia, and often loss of sexual power. Pains in the loins, irritability of bladder, and high specific gravity of the urine—generally from 1.025 to 1.030,—with various symptoms of impaired health, are also commonly experienced. The urine is invariably acid, often excessively so; and there is a marked tendency to eruptions of boils. Dr. G. B. Runc notes that he has seldom met with phthisis in cases with oxalate of lime deposit, and that in very few instances has he seen oxaluria terminate in the formation of a calculus. He again states that the source of this deposit is to be imputed to metamorphosis of the tissues, and that this is the only way that the attending emaciation can be satisfactorily accounted for. It may be inferred that the deposit as well as the emaciation are the results of impaired or morbid assimilation of the food, and the consequent imperfect nutrition of the tissues (§ 70.).

72. f. Causes.—This state of the urine is frequent in those who are subject to mental anxiety and to laborious mental occupations, more especially in men on the stock-exchange, in medical men, in barristers and solicitors, and in those who are engaged in occupations attended by much mental anxiety, and are excessively devoted to business or study. The exciting causes are chiefly neglect of health, chronic dyspepsia, hypochondriasis, exhaustion from disease, from phthisis or mercurial courses; venereal excesses, masturbation, involuntary seminal emissions, excessive discharges, and prolonged lactation, previous acute diseases, injuries affecting the spine, &c.

73. g. The Treatment of oxalate of lime deposits is generally successful, if the diet and the regimen of both mind and body be duly regulated. The food should be digestible, properly cooked, and the animal and vegetable in due proportion. Malt liquor ought to be avoided; and either a small quantity of brandy in much water, or a glass of dry sherry in two of water, may be taken with dinner. The medicines most appropriate are the nitric or nitro-hydrochloric acid (one part of the nitric to two of the hydrochloric) given in tonic infusions or decoctions. If anaemia or chlorosis exist, the tincture of the muriaie of iron, with preparations of columbus or quassia; or the mixture ferri composita, or the ammonio-citrate or ammonio-tartrate of iron, should be prescribed. If the bowels be costive, the extract of taxacum may be given with the former medicines; or the decoction of aloes be conjointed with the mixture ferri composita; or the mixture gentiana composita may be given alone, or with tincture of serpentina, &c. The sulphate of iron, or of quinine, or of zinc may be prescribed, where the foregoing fail, combined with small doses of camphor and henequen, or of cinchon. Dr. G. B. Runc recommends, recourse to colchicum for oxaluria, and states that, under the influence of this drug, copious deposits of oxalate of lime have become replaced by uric acid and the urate of ammonia, thus inducing a condition of urine much more amenable to treatment.

74. v. Chemical Pathology of Urine Salts in the Urine.—Phosphoria—Phosphate of Lime, Ammonia-phosphate of Magnesia, and Carbonate of Lime. Phosphoria. Phosphoric acid is excreted in considerable quantity from the blood by the kidneys, combined with soda, ammonia, lime, and magnesia; forming, most probably, ammonio-phosphate of soda, phosphate of magnesia, phosphate of lime. The first of these is soluble in water, and Dr. G. B. Runc considers it to be the solvent of uric acid, and indirectly the source of the acidity of urine. The other two salts are insoluble, but the presence of a minute portion an acid, even the carbonic, enables water to dissolve a considerable quantity. They are also soluble to some extent in hydrochlorate of ammonia. "In healthy urine the earthy phosphates are held in solution by the acid of the superphosphates, produced by the action of uric (or hippuric) acid on the tri-basic alkali salts; and these salts are also, according to Erdelius, capable of dissolving a quantity of phosphate of lime." The earthy phosphates are always abundant after a meal, the reverse applying to the alkaline salts. Phosphoric acid may be excreted in large excess without forming a deposit, owing to its combination with an alkaline base; and hence, when the excretion of an excess of this acid is looked for, it is not indicated by the amount of earthy salts deposited, for there is always three or four times more phosphoric acid in a given specimen of urine, in the form of a soluble alkaline salt, than is precipitated as an insoluble earthy compound. The presence of an excess of lime and magnesia has more to do with determining a deposition of insoluble phosphate, than an excess of phosphoric acid. The circumstances under which the earthy phosphates are deposited often are of so great importance as to require a recognition of their existence, as well as of the quantities of these phosphate deposits.

75. A. The Diagnosis of Earthy Phosphates. — a. Deposits of these phosphates are white, unless coloured with blood, are soluble in dilute hydrochloric acid, and insoluble in liquor potass and in ammonia. On heating the urine, the deposit merely agglomerates into little masses. A small quantity of a solution of sesqui-carbonate of ammonia added to a large quantity of healthy urine causes turbidity, from a deposit of the triple phosphate mixed with some phosphate of lime. On placing a drop of this turbid urine under the microscope, myriads of minute prisms of the triple salt, mixed with amorphous granules of the phosphate of lime, will be seen floating in the fluid; these disappear on adding a drop of any acid. As these earthy salts are insoluble in water, they must be held in solution in the urine by the free acid which generally exists. If from any cause the quantity of solvent acid falls below the necessary proportion, the earthy phosphates appear diffused through the urine, disturbing its transparency, and subside, forming a deposit. Hence, whenever the urine is alkaline, phosphatic deposits are necessary consequences. If urine be secreted with so small a proportion of acid as barely to reddite litmus paper, a deposit of triple phosphate often occurs within a few hours after emission; probably owing to the presence of
mucous matter, which induces the decomposition of urea and the formation of carbonate of ammonia, which, by neutralising the solvent acid, precipitates the phosphates. The triple phosphate, which occurs spontaneously in prismatic crystals, is a neutral salt, "and may exist as a deposit with very sensible acidity of the supernatant urine. It by no means follows that the existence of a deposit of this salt involves the necessarily alkaline state of the urine." Another triple phosphate, differing from the former in containing an excess of base, is of frequent occurrence in the urine when in an alkaline or putrescent state. It cannot be present in urine having the slightest acid reaction on litmus paper. Its crystals are invariably stellar or follicose. This salt is termed the basic phosphate. "When the triple or calcareous phosphates are separately exposed to the heat of a blowpipe flame, they fuse with great difficulty, and not until the heat has been urged to the utmost. If, however, the phosphate of lime is mixed with a triple phosphate of carbonates, they readily melt into a white enamel. These mixed salts constitute what is hence termed the fusible calculus, and they can readily be detected by this property in concretions; a character very available in the examination of gravel and calculi, as the two phosphates generally occur together."

76. b. The Physical Appearance of deposits of the earthy phosphates varies remarkably. Sometimes they appear as a white crystalline gravel, especially when the triple salt is the chief part of the deposit. But if a small quantity be present, it may readily escape detection by remaining a long time diffused in the urine. After a reposi of a few hours, some of the crystals collect on the surface, forming an iridescent pellicle, "reflecting coloured bands like a soap bubble or a thin layer of oil. If then the lower layers of the urine be placed on a watch-glass, and held obliquely over the flame of a candle or any strong light, a series of glittering points will become visible from the reflection of light from the facets of the minute prisms of the salt." (Op. cit. p. 269.)

77. The phosphates often subside to the bottom of the vessel like a dense cloud of mucus, for which they are mistaken. Sometimes they form, in very alkaline urine, dense masses, hanging in ropes, like the thickest puriform mucus, from which it is impossible to distinguish them by the unaided eye. Their disappearance on the addition of hydrochloric acid shows at once their nature. If the examination of a few drops of the urine between two plates of glass, by the microscope, will detect the characteristic crystals of the phosphates. Occasionally they are mixed in a deposit with the urate of ammonia, this latter being pale or nearly white. As phosphatic urine is usually very pale, it follows that any urate of ammonia deposited from it will be nearly white from the absence of colouring matter.

78. c. States of Phosphatic Urine. — Although it may appear necessary for the urine to be alkaline for a deposit of phosphates to exist, yet generally urine which deposits the triple phosphate is acid at the time of its excretion. Some neutral salts redden litmus paper, and yet contain no free acid; and this fact may in some cases explain the occasional acid reaction where deposits of phosphates exist. Dr. O. Rees has shown that hydrochlorate of ammonia may in some cases be the solvent of the earthy phosphates when in excess. Occasionally urine does not contain any visible deposit, and yet on the application of heat appears to conglutate from the deposition of earthy phosphates. The addition of a drop of nitric acid immediately dissolves this deposit, and distinguishes it from albumen. The precipitation of the earthy phosphates by heat has been ascribed by Dr. H. Beer to the existence of carbonate of ammonia in the urine in a free state. Dr. B. Jones has, however, shown that, if to any urine rich in phosphates, as that passed shortly after a meal, a minute portion of an alkali be added to neutralise any great excess of acid, the subsequent application of heat precipitates the earthy phosphates.

79. Generally where phosphatic deposits, magnesian, calcareous, or both, exist for a considerable time, the urine is pale, often whey-like, passed in large quantities, and of low specific gravity—from 1·005 to 1·014. "This is especially the case when hunger, they read, of the time exists." On the other hand, when the deposits recur and disappear in the course of a few days, the urine is generally of a deep amber colour, is of high specific gravity (from 1·020 to 1·030), often contains an excess of urea, and presents an iridescent pellicle on its surface by reason. This form of phosphatic urine is often met with in connection with irritative or inflammatory dyspepsia and with mal-assimilation. Sometimes prisms of triple phosphate are seen entangled in the meshes of a mucous cloud for a day or two, and then disappear. Phosphatic urine occasionally varies from a whey-like hue to a deep brown or greenish brown, is very acid, generally alkaline, and loaded with a denseropy mucus often tinged with blood, and in which large crystals of the triple phosphate and amorphous masses of phosphate of lime are entangled. This variety is almost always met with, either under the irritation of a calculus, or even of a catheter worn in the bladder," or where actual disease of the mucous coat of this organ exists.

80. d. For the microscopic characters of earthy phosphates, I must refer to Dr. G. Bigni’s work, from which I own the following:

"1st, the prisms of neutral triple phosphates; these are well defined, the triangular prism being the form most frequently met with, but it presents every variety in its terminations; — 2nd, simple stellate of the neutral salt, the radii being more or less distinct or crowded; — 3rd, penniform crystals of neutral salt; this variety presents the appearance of striated feather-like crystals, two being generally connected resembling a pair of wings; — 4th, stellar and follicose crystals of basic salt; this variety is chiefly formed after the urine is discharged, and, when rapidly formed, it generally appears as six-rayed stars, each ray being serrated.

Phosphate of lime generally presents no appearance of crystalline structure; it either resembling an amorphous powder, or being collected in rounded particles, often adhering to prisms of triple phosphate."

81. B. Pathological Relations of the Phosphates.

"I have many years ago contended, and more recently, in various parts of this work, alluded to the fact, that the secretions are endowed, to a certain extent, with an emanation of vitality,
URINE & URINARY DEPOSITS—PATHOLOGICAL & THERAPEUTICAL RELATIONS OF. 1215

which, for a time, resists the changes which they are disposed to enter into either when organic nervous influence is much depressed or when they are removed from the body. "Indeed, the vital influence modifies their physical conditions, in a more or less marked manner, as long as they continue subjected to its operation. From this source, also, they are imbued with a vital emanation, the presence of which is indicated by the continuance, for a time, of the specific characters of each. This emanation, being no longer required when they are removed from the body, is soon dissipated. The secretions, while within the sphere of the animal system, and for a short time afterwards, possess this emanation of the vital influence, in an amount sufficient to give them certain characters, and to preserve them from the chemical changes to which their constituents are naturally prone; but when this influence becomes depressed, or ultimately ceases, they then undergo dissolution as unequivocal as that evinced by the textures of the body. In confirmation of this view, I need only refer to the comparative conditions of the more perfectly elaborated secretions immediately after their discharge, and after periods of various duration have elapsed from the time of their discharge from the body." (Physiol. Notes by the Author, p. 636.).

82. The above doctrine was published by me in 1824; and both then and subsequently I have insisted upon its importance, and upon the obvious deductions which follow from it. Whilst vital energy is perfect, or at least not materially impaired, the secreted fluids, especially whilst they remain undischarged from the body, are preserved by this emanation of vital influence from those changes to which their constituents are chemically disposed. But if these fluids are retained for an unusually lengthened period, or if vital energy, to which they owe their original natural character, be much impaired, those changes which their constituents are chemically disposed to undergo, take place more rapidly after their discharge from the body, and in many instances even whilst they still remain in those receptacles or cavities which are provided for their reception and temporary retention. But with the various manifestations of depressed vital power, changes in the secretions are not only such as take place after these secretions have been reduced, but also those which occur during their production, and which depend upon the existing state of vitality throughout the body, and upon the manifestations and modifications of vitality in the organs especially destined to the formation of these secretions. When vital energy is impaired, or, in other words, when debility is manifest, whether constituting the only or chief pathological condition or associated with others, as with nervous susceptibility or irritability, or with febrile action, or with organic change, or with other alterations further impeding or disturbing the functions of a secreting organ or organs, results will be furnished by the secretions varying with the manner in which the general impairment of vital power affects the functions of digestion, assimilation, nutrition, and waste—the successive conditions of nutritive supply, of vital cohesion and muscular dissociation, of vascular depuration, and of ultimate discharge.

83. This doctrine, which, as I have shown, has been published and taught by me with reference especially to the several secretions and excretions—recrenemients, excrementitious, or deparuring—is altogether applicable to the urinary excretion, and to the deposits which form in it, both after and previous to its discharge from the body, and in a more particular manner to the urine which furnishes the phosphates in great or unusual excess. The deposit of early phosphates may be viewed as resulting more especially from depression or exhaustion of vital power, as manifested chiefly by the nervous system, and is hence most frequently met with in the aged, and in those who labour under disease of the cerebro-spinal nervous system, or have experienced injury of the spine, or have suffered much from tear and wear of mind and body. The pathological conditions giving rise to the deposits of phosphate of lime, are similar to those producing the triple salt. Indeed, they often occur simultaneously, especially when the urine is alkaline. Dr. G. Birk considers that, when the deposit has consisted chiefly of the calcareous salt, the patients have presented more marked evidence of exhaustion, and of the previous existence of some drain on the sympathetic nervous system, than when the triple salt alone existed, unless its source is strictly local.

84. When the triple phosphate occurs in small quantities, nearly or quite free from the phosphate of lime, the urine being acid or neutral at the time of emission, the cases are then the slightest of this class of disorders. Nevertheless, severe dyspepsia, irritability, restlessness, impaired assimilation and emaciation are constantly present. When there is an excessive discharge of urea, the symptoms are more severe, and the exhaustion and nervous depression greater. The urine is then of a rich amber colour, generally depositing phosphates on the application of heat, and of a specific gravity varying from 1.025 to 1.030. In mild cases of dyspepsia, especially in the gouty diathesis, an iridescent pellicle of triple salt, the urine being rich in urea and either acid or neutral, is often observed. This state of the urine is not infrequent in dyspeptic females at or about the climacteric period. Crystals of the triple salt occur in very old persons, especially in the ill-fed; persons recovering from acute diseases, especially from rheumatic fever.

85. Early in continued fever the urine is high-coloured, and loaded with uric acid and urates. It is then generally acid; but after the end of the second week, or earlier, in the lower types of fever, the acidity often vanishes, and the urine becomes alkaline and deposits the phosphates. This is, however, more frequently seen in some types and states of fever than in others, especially in the typhoid and phthisy-adynamic, and when comatose symptoms appear. The treatment, particularly the use of alkaline medicines, of or the salts of the vegetable acids, has some influence in favouring the change to an alkaline state of the urine. In these cases, as well as in other diseases where the nervous energy is remarkably depressed or exhausted, more especially in the low forms of insanity, in cases of debility from venereal excess, masturbation, &c., after injuries of the spine, as remarked by Pouret, Baun, and others, the elements of urea deposition, rearranged, or obedient to ordinary chemical affinities, and form carbonate of ammonia.

86. When the deposit of phosphates is excessive,
the two phosphates are generally mixed, either falling to the bottom of the vessel, or remaining suspended in the urine like mucus; the urine is then generally alkaline, and of a yellow ammoniacal or putrid. This kind of urine is most remarkable in organic disease of the urinary organs, or serious affections of the spinal chord followed by such disease. Conformably with the doctrine above insisted upon (§§ 81—5.), the impaired vitality of these general alkaline urines may impair the vitality of the frame generally, as in typhoid and putro-adynamic fevers, or of the urinary organs especially, as after injuries or diseases of the spine, its chord, &c., so affects the uriniferous secretion, both during the performance of this function, and whilst the secretion is retained, as to favour the occurrence of those changes, even before it is discharged, which its ordinary chemical affinities dispose it to assume. The change thus produced in the urine, may be followed by the formation of calculi in any part of the urinary apparatus, but most frequently by irritation of the ureteric mucous surfaces and by the formation of calculi of uric acid, which may become puriform or changed, by the carbonate of ammonia formed in the urine, into a viscid and almost gelatinous or tenacious ropy fluid, sometimes preventing the discharge of the urine, and increasing the sufferings of the patient. Mr. Curll's view of this subject is different from that now stated. He believes that the result of the spinal lesion is the loss of the natural sensibility of the bladder. The effect of this is the secretion of unhealthy ascleiscent mucus, which acts chemically upon the urine, renders it alkaline, and leads to the deposition of the earthy phosphates. He thinks that the urine may subsequently be secreted in an alkaline state by the extension of the irritation from the bladder to the kidneys, or by the latter sympathising with the former. It should not, however, be overlooked, that injury of the spine not only deprives the urinary apparatus of that share of nervous power reinforcing the organic or ganglial nervous influence which endows this apparatus, but thereby also modifies the secreting function of the kidneys. Whether the result be impairment only, or a modifying action, the same effect will be produced, that the chief result of these injuries is paralysis of the bladder, especially as respects its contractile powers, causing retention of the urine, which, whether it be secreted in an altered or morbid condition, or rendered such after its secretion, owing to impaired vital influence, more readily irritates the urinary mucous surface, than in its healthy state, and gives rise to mucous discharge and the consequent lesions of the urinary organs.

87. The urine may be alkaline and loaded with phosphates owing to disease of the Urinary Bladder (see that article), more especially of its mucous surface. This state of the urine thus arises from three important pathological conditions: — 1st, from vitreous dehiscence, as manifested chiefly by nervous debility and irritability; — 2nd, from injuries and diseases implicating the spinal chord or its membranes; — 3rd, from disease of the urinary organs. But it should not be overlooked that the second condition affects the urine by first disordering the functions and subsequently the structure of these organs. It is important to be able to distinguish between these sources of alkalinity of the urine, especially between the presence of a general morbid condition, and a strictly local disease. Dr. Bence Jones has established, that urine is alkaline from ammonia when the cause is local, and from a fixed alkali when the ailment is general. Hence urine may be alkaline, and not ammoniacal, although when the latter it is necessarily the former. The urine is sometimes alkaline after breakfast, owing to the presence of a fixed alkali carbonate. The urine, in such cases, turns red linen or depressed vitality of the frame generally, as in typhoid and putro-adynamic fevers, or of the urinary organs especially, as after injuries or diseases of the spine, its chord, &c., so affects the uriniferous secretion, both during the performance of this function, and whilst the secretion is retaine...
URINE & URINARY DEPOSITS—PATHOLOGICAL & THERAPEUTICAL RELATIONS OF, 1217
dependently of affection of the spine or of the urinary organs, the treatment should be directed rather to the constitutional, digestive, and assimilative disorders, than to the state of the urine, which ought to be viewed only as a symptom. In these cases, depression of spirits, hypochondriasis, and various dyspeptic symptoms are present; and the urine has a high specific gravity, contains an excess of urea, and deposits crystalline or amorphous phosphates. In these the urinary deposits should be viewed as the results of defective vital and nutritive powers, and as exhausting the nervous energy; and the treatment ought to be directed to the functions of the stomach and bowels, and to the improvement of the general health, by means of stomachic or tonic aperients, by a light, digestible, and generous diet, and by bitter infusions or decoctions. To remove the more painful symptoms, the oxide of bismuth or of zinc may be given with the extract of ox-gall, and also the extract of percyannate of iron; and two black, melanuric, and melanic acid, have been distinguished. These colours as well as green have been mentioned by many of the older writers noticed in the bibliography; and have doubtless been owing to the presence of blood or bile altered by the urine.

94. (a) Quinacrine was discovered by Baccovez, and noticed by several more recent observers. Urine containing it is of a deep blue colour, the colouring matter being deposited by rest, and readily separated by the filter. The origin of this substance, as well as its pathological indications, if any, are obscure, and merely furnish a subject of conjectural discussions to chemical pathologists.

95. (b) Indigo is sometimes prescribed empirically in some diseases, as epilepsy; and it may thus pass into the urine, and form a blue deposit. Flouart and Simón have shown that it may be generated in the economy, the urine acquiring a dark blue colour, and depositing a substance of the same hue, which, when collected on a filter, presents all the characters of indigo. The origin and pathological indications of this substance, when not taken internally, are unknown.

96. (c) Prussian blue, or secoqui-jerse-quainide of iron, has been found in the urine of patients taking the ferro-cyanide of potassium upon preparations of iron. It furnishes no pathological differences.

97. (d) Melanurine and melanic acid are black pigments which have been rarely met with in the urine. It is probable that they are merely the colouring matters of the blood altered by the state of the urine. Many years ago a clergyman in London, with whom I was well acquainted, experienced a dangerous immersion in the river, and was saved with difficulty. He soon afterwards began to pass black urine, for which I was requested to visit him. He complained only of a slight weight in the region of the kidneys. The urine was quite black, was passed in about the usual quantity, and was retained nearly the usual time. The lower extremities were not affected. A portion of the colouring matter was deposited, but the superannuated urine was not materially altered from its black colour. I attributed the colour to the escape of red globules of blood with the urine, owing to congestion of the kidneys, and their alteration by the state of the urine. Conformably with this view, I directed blood to be taken from the limbs by cupping.

VOL. III.
afterwards resumed its healthy appearance, and no further complaint was made.

98 xi. Organic Deposits in Urine.—The deposits in the urine which have been noticed above are recognisable by their forms and chemical properties; those which remain to be mentioned, either possess, or have possessed, organisation, and can be distinguished only by an examination by means of the microscope, or of tests.

99. A. Blood and its Elements are often seen in the urine, and suggest important pathological and therapeutical indications. The urine may contain only the serum of the blood, or liquor sanguinis; or with this a considerable proportion of red globules; or it may contain a very large proportion of blood, hardly or not at all changed from its normal characters.

100. (a.) Serous or albuminous urine is readily indicated by heat, and by adding a drop of nitric acid, which coagulates the albumen contained in it. Urine containing much albumen is either free from, or contains but a very small amount of, colouring matter. The reddish urine in granular disease of the kidneys furnishes less albumen by heat than the straw-coloured. Nitric acid and a mixture of one part of each of these with three parts of hydrochloric acid, are more delicate tests of the presence of albumen than heat. Several sources of fallacy have been pointed out by writers which should not be overlooked when resorting to these tests:—1st. Heat will produce a white precipitate in urine containing an excess of earthy phosphates; but this will disappear on adding a drop of nitric acid, and distinguish it from albumen. 2nd. Nitric acid will produce white deposits in patients taking copaiba, cubeb, or other resinous substances; but heat has no such effect. 3rd. Nitric acid will, in some instances, produce a buff-coloured amorphous deposit in the high-coloured urine in fever, but heat does not cause this change. 4th. Albumen combined with alkalies does not coagulate by heat; therefore nitric acid should be used if the urine be alkaline. 5th. Albumen in an incipient state may not be detected by heat, but readily by means of the acids.

101. Albumin. as it is found in the urine in a coagulated state, presenting a tubular vermicular appearance, being casts of the unirniform tubules of the kidneys, often with portions of epithelium adhering to them; and, according to Dr. G. Johnson, loaded with fatty globules. These casts, when recently passed, appear like large hairs; but form after a time a dirty-white sediment, which a solution of potash gelatinises, and distinguishes from mucous. This deposit is pathognomonic of the changes which terminate in granular disorganisation of the kidneys.

102. Blood passed in considerable quantity in the urine, may either be more or less intimately mixed in the urine or it may have coagulated in blackish masses like pieces of black-current jelly, linear masses like leeches being passed through the urethra with great suffering. In the former case the blood generally is poured out in the kidneys or their pelvis; in the latter it is most frequently effused, either in very small quantities of blood, in this case when the urine is always more or less coloured, often so deeply as to present a port-wine colour; the microscope showing some entire blood-globules, and others with their investing membrane broken down, and their coloured contents diffused in the urine. If the quantity of urine be small, the urine may appear like the washings of meat, or of a dirty or dingy hue, the red-globules being still recognisable by the microscope. The coagulation of the urine by recent sordidness occurs; it is owing to the presence of fibrin, which, however, is very rarely effused without an admixture of blood-globules, giving the coagulum a reddish colour, or, of a fatty matter, imparting to it a whitish or paline hue.

103. Haematoxine, or the colouring matter contained within the sacs of the blood-globules, imparts to the urine a deepness of tint in proportion to the quantity of the colouring matter which has escaped from the sacs of the blood-globules, or rather to the number of these globules which are ruptured. Generally, however, the urine, when recently voided, contains some globules that remain entire; and, with the colouring matter, more or less albumen, which is affected, as shown above, by heat and nitric acid, excepting that the coagula are more or less brown owing to the presence of haematoxine. When, however, the urine is much loaded with purpurine, or wite acid, or with bile, these may be mistaken for haematoxine. The mixture is more or less affected in colour or transparency by a boiling heat; the second is not affected by heat, and is at once distinguished by the characters of the deposit; the third may be detected by pouring a thin layer of the urine on a white plate or sheet of writing paper, and let a drop or two of nitric acid to fall upon it, when a change of colours, in which green and pink predominate, will be produced. Haematoxylin, purpurea, chimaphilin, and soura, the former especially, will impart a reddish or brownish hue to the urine; but these will be distinguished from haematoxine by the knowledge of their having been taken, by the black precipitate produced by sulphate of iron when the first of these has produced the redness; and by the absence of albumen and haematoxine as regards all of them.

104. The presence of blood-globules in the urine is best determined by the microscope. If the blood be recently effused, they will either be found adhering in roundels, or uniliated in figure. But if it have been effused for some time, or if the effusion has been slow, or the exudation of an asthenic character, the linear arrangement of the globules is lost, the investing membrane, being ruptured, is collapsed around their corpuses or nuclei, and ultimately the globules appear irregular in their margins.

105. (b.) The pathological indications of the presence of the elements of blood, or of blood in any form, in the urine, has not always been of importance, but it has become of even greater importance to the physician since the enlightened investigations by Dr. Bright of the diseases of the kidneys. When pure blood, or even the admixture of its globules in large quantity, is observed in the urine, it may be presumed that active or passive hemorrhage from some part of the urinary passages has occurred; the more pure the blood, and the less intermittent, the more probable is the effusion to have taken place in the lower passages of the apparatus. If the quantity of haematoxine be so small as to tint the urine, it is to be presumed that both it and the albumen also present result from the congested
URINE & URINARY DEPOSITS.—Pathological & Therapeutical Relations of. 1219

state of the kidneys connected with the cachectic inflammation of these organs, which terminate in the organic change which renders them incapable of eliminating the nitrogenised elements of urine and of deputing the blood, although the secretory power is so far preserved as to separate the albumen and water, this latter element being ultimately very incompletely removed. (See Art. KIDNIES, § 83 et seq.)

106. When the presence of Albumen in the urine was first shown to be a proof of granular disease of the kidneys, I contended (see Art. Dropsy, § 36 et seq.), that this state of urine existed in several other diseases, especially in the febrile and exanthematic maladies of children, and, when congestion of the kidneys is occasioned by other affections or circumstances, although not always or continuously observed, that yet it was a contingent and occasional or temporary occurrence. Since this statement was made, from a varied observation, the truth of it has been confirmed by many subsequent observers, and we perceive, when the globule becomes large quantity is found to be filled with several transparent bodies or nuclei.

Hence the pus-globule is a regularly organised body, consisting of a granular membrane enveloping transparent nuclei, being, in other words, a nucleated cell. (See Disease, §§ 131, 132, and the Microscopic Characters more fully in the Art. Pus, and in Urinary Bladder, § 48.)

111. C. Mucus is present in healthy urine in very small quantity. When irritation exists in any part of the urinary apparatus the mucus is greatly increased, and generally in proportion to the amount and extent of it; this secretion varying from a flocculent clouds in the urine to the production of a fluid so viscid as to form a copious papyraceous deposit.

This condition of the urine is generally alkaline, and undergoes a putrefactive change soon after it is passed, or even before being voided if it be long retained. Although it be acid when passed, it rapidly becomes ammoniacal. Mucus contains no albumen admitting of cohesion only by heat or nitric acid (§ 100.), and hence mucous urine simply “can never be albuminous like pus, unless the albumen be derived from some other source.

Agitated with ether, mucus gives merely traces of fat, and in this respect also differs from pus.” (For the pathological and therapeutical relations of Mucus Urine, see the Art. Urinary Bladder (§ 47 et seq.).

112. D. Epithelium.—Exfoliation of the epithelial covering of the genito-urinary mucous surface is constantly taking place, but with very different rates of rapidity. This covering is sometimes partially detached, so as to appear like patches of membrane-like mucus; some of the epithelial cells being irregularly lacerated, others entire, and readily recognised by the aid of the microscope. When suspended by fluid they are oval cells which become irregularly angular and flattened when partially exposed. When quite empty they present in each a central nucleus projecting above the surrounding surface. These cells are said sometimes to contain fat globules, especially in the Morbus Brightii. When the exfoliation of epithelium is copious, a deposit is thereby formed in the urine, resembling mucus, but differing from it in the form of the deposit. With liquid potash this deposit gelatines nearly as perfectly as when pus is present. When an

412
abundance of epithelium is found in the urine, oxalate of lime often also is present; the irritation of the mucous surface of the urinary passages, especially in the kidneys, very probably at the same time that it detaches the epithelium, converts the uric acid and urates into the oxalate.

113. Spermatozoa, or what has been called spermatic animalcules, are sometimes found in urinary deposits, when the urine of the male adult has been allowed to repose for a time.—a. The only means of distinctly determining the presence of semen in the urine is by ascertaining the existence of spermatozoa by the aid of the microscope. These minute bodies never occur living in urine, unless protected by the presence of a deposit of pus, in which they retain their power of moving a long time after emission. In the microscope the spermatozoa will be observed as minute ovate bodies, provided with a delicate bristle-like tail, which becomes more distinct on allowing a drop of urine to remain on the slide for some time. These are generally found round granular bodies, rather larger than the body of a spermatozoon, and nearly opaque from the numerous asperities on the surface of the investing membrane. These appear to be identical with the seminal granules described by Wagner and others. (Op. cit., p. 359.)

114. The presence of spermatozoa in the urine furnishes certain Pathological Indications of much importance. They may be present owing to the discharge of urine immediately or soon after seminal emission, the urine washing away the portion of semen which may remain in the urethra; or owing to a contusive motion having pressed upon the spermatic receptacles, so as to press out a portion of their contents. However the presence of these bodies in the urine may be accounted for, the fact that they are commonly observed in persons who have weakened their sexual organs, either by excessive female intercourse, or by the unnatural vice of masturbation, is indisputable; and in such persons chiefly or only spermatozoa, and the much discussed affection of spermatoorrhica, is observed. The pathological and therapeutical indications furnished by this condition of the urine under the head of Impropriety, and more fully under that of Pollution, voluntary and involuntary.

115. F. FATTY OR OILY MATTER has not infrequently been found in the urine, generally, however, in minute traces only, and very rarely in any considerable quantity. It is most probable that some of the instances, in which oil has been said to have existed in the urine, have been those in which the oil-like pellicles of the earthy phosphates have formed on the surface of the urine. The genuine states of fatty urine have generally resembled milk in colour and opacity, and have gelatinised on cooling. The term chylous urine has been applied to these states by Dr. Pusheg. Dr. Elicholze and Dr. G. Johnson contended that oil or fat existed in the urine in granular disease of the kidneys, owing to the superabundance of fat in the epithelial cells of the tubular structure of the kidneys, and to the escape of these from the tubules with the urine. But the quantity of fatty matter thus mingled with the urine is rarely such as to give rise to appearances indicative of its existence, unless the deposit be examined under the microscope, when the cells containing oil, sometimes presenting casts of the tubes, from which they have been detached, may be observed.

116. In most cases of chylous urine, albumen is present in very varying quantity, and forms with the fat an intimate admixture or emulsion. The fat may be obtained by agitating the urine with an equal quantity of ether in a tube. The presence of fat in albuminous urine may be viewed as a strong indication of organic disease of the kidneys; but the combination rarely exists in such a manner as to give rise to the chylous appearance of the urine. It should not be overlooked, that instances sometimes occur, in which hysterical females, to create interest in their cases, or to obtain other ends, have imparted a morbid appearance to their urine, by adding to it milk, or small quantities of blood, or other matters, by which the medical attendant has been deceived. Such instances have come before me and other physicians with whom I have rarely seen cases of chylous urine. The most remarkable instance of it which I have observed was in a mulatto young man from the West Indies, Dr. G. Bird states that, in the chylous urine he has examined, he has failed in detecting under the microscope the slightest appearance of colloglobules, blood-dies, or pus-granules; the opacity appearing to depend upon the presence of particles so minute as to present no defined form. M. L'Heritier has, however, remarked that oily globules can always be detected in fatty urine; and Dr. Simon, of Berlin, has made the same remark, and has stated that he has met with three varieties of fatty urine; one in which the fat is merely diffused through it, and collects on its surface by repose, as in cases recorded by Dr. Elliotson; the other in which the fat is combined with albumen; and a third, in which the fatty matter exists with casein as an emulsion forming the true milky or chylous urine. Dr. Bence Jones has investigated this state of the urine, and has arrived at the following conclusions respecting it:—

1st. The fat on which the milky aspect of the urine depends appears after the absorption of fat and uric acid, and alkali salts, may be found even when no food has been taken, and consequently no chyle formed.

2nd. During absolute rest, albumen disappears from the urine, and does not reappear in any quantity, even after taking food, unless active exercise is employed. A short time before rising early, the urine gelatinises by repose, but is free from fat.

3rd. This state of urine does not depend upon the presence of an excess of fat in the blood as proved by actual analysis.

4th. The seat of this disease is probably some slight alteration in the structure of the kidneys, by which, when the circulation through these organs is most active, one or more of the constituents of the blood exude from the capillaries and escape into the urine.

Dr. G. R. Boyd, of Demerara (Dr. G. Bird states), has observed cases of chylous urine so frequent in creoles and negroes as to be often epidemic in that country. This state of the urine appears to be attended by general debility and emaciation as in diabetes. He attributes the disease to lesion of the assimilative functions; and he treats it by the free administration of a decoction of the mangrove bark (Rhizophora racemosa).
This medicine acts freely on the skin, increases the secretion and alters the character of the urine, and improves the general health.

117. G. CONFERNOID GROWTH.—Torula Cer- 
viciae.—Fungoid Growth.—Vibriones, &c., have 
been described as existing in the urine, in certain 
states of the frame, chiefly characterized by remark-
able depression of vital power. The existence of 
these may be imputed to the presence of albumi-
nous, flocculent, saccharine, or other matters in 
the urine, and to changes which have taken place 
in these after the urine has been discharged, al-
though they may possibly be formed in the blad-
der, when the urine is long retained in these mor-
bid states in this viscus, especially when the vital 
energies are very much depressed, and the other 
circumstances favourable to these productions al-
ready adverted to (§ 82) are present.

118. I. HYDATIDES have been passed in the urine; 
but cases in which they thus have been observed 
are extremely rare. Instances have, however, 
been recorded in the Philosophical Transactions 
(No. 273) and in the Medical Observations and 
Inquiries by Mr. Russel (vol. iii.). A case 
came before me many years ago, in which a num-
ber, varying in size from a small pea, to that of 

diverse, were passed, in the course of two or 

three days. Soon afterwards the case passed 
from under my observation, without being able to 
ascertain its issue.

119. XII. FOREIGN BODIES.—Worms, &c., have 
been often found in the urine, in some cases in 
consequence of having been introduced into the 
bladder, in others from having been put into the 

t he urine with the intention of deception; and, in 

more instances owing to their passage by ulcer-

ation, penetration, or otherwise, through the pa-
riz, or a portion of the digestive canal, or 

ominal parasites. Whoever may be desirous of 

surpassing cases of this description will find a 

umber of them related in the Ephemerides of 

atural Curiosities, and in the Memoirs of the 

rench Academies, and various other works en-
named by Pluquet and Reuss.

120. IV. GRAVEL.—Urinray deposits, such as 

are above described, are formed on the cooling of 

in the urine, and either loose and pul-

ulent, or more concrete, crystalline, or sand-

like. These deposits, although associated with, or 

ymptomat of, various diseases, may occasion, 

as respects their effects upon the urinary organs, 

but little disorder. But when deposits are formed 
in the warm urine within the urinary apparatus, 

owing either to the quantity of these matters con-

ained in the urine, or to changes in the states of 

their constituents, or of temperature, vital endow-

ment, &c., and are discharged with the urine in 

the form of a fine powder, or of crystalline sand-

like particles, or of small masses, then the disease 

is termed gravel, and the symptoms are sometimes 

very severe.

121. The discharge of such gritty matters as 

these with the urine is usually attended by sym-

toms of irritation, and pain in the regions of the 

knees, urinaries, bladder, and in the urethra, 

thereby constituting whilst characterizing the 

condition commonly denominated gravel. The 

signs of irritation may be slight, or they may be 

severe in one or other of the situations just named, 

or even in two or more of them. But the signs, 

as well as the causes which produce this condition 

of the urine, are the same as those which attend 

the formation of calculi in the urinary apparatus, 

although they are very frequently much less se-

vere. The chemical constitution of the gravel 
discharged is generally the same as that of urinary 
calculi; the difference consisting chiefly in the 

constituents precipitated from the urine being dis-
tached or incoherent, or forming numerous minute 

crystals, instead of large concretions, of many 

concentric layers. In the former case, the de-
posits within the urinary organs are washed away 

by the urine before they have been sufficiently 

long retained to concretize into a nucleus, or to 

become a large calculus—or to assume the 

characters now to be described.—CALCULI. The 

Treatment of gravel is manifestly the same as 

that recommended for urinary deposits and Urin-

ary Calculi. (See § 179 et seq.)

122. V. URINARY CONCRETIONS OR CALCULI.— 

Correct views as to the composition and formation 
of urinary concretions or calculi are of comparatively 

recent date. Previously to VAN HELMONT these 

calculi were believed to be derived from mate-

ners contained in the food and drink; but he con-

tended that they are not formed from these sources. 

HALES confirmed the opinions of VAN HELMONT 

as to the differences between urinary concretions 

and common stones, and first directed attention to 

the discovery of a solvent for these concretions. 

BOYLE, WHYTT, ALSTON, SLARE, and others, 

sequently speculated on the subject of solvents 

for calculus. WHYTT proposed lime-water for 

this purpose; and ALSTON contended that, al-

though lime-water is of some service in urinary 

sufferings, it is not a solvent of calculus. At 

the commencement of the last century the Leyden 

School of Medicine taught more correct doctrines 

of the formation of urinary concretions than had 

previously been entertained; and showed that 

these nuclei were derived from the kidneys or 

from the bladder. VAN SWieten contended that 

the elements of calculi exist in the urine of men 

the most healthy, and that if the urine be ele-

vated before these elements concur in the forma-

tion of a concretion, no such production takes 

place. He considered that the concurrence of the 

elements in the form of a concretion, and of a 

more or less slowly in different persons; and that 

according to the rapidity or slowness of such forma-

tion, the concretions are formed either in the 

kidneys or in the bladder. In 1776 SCHELLE 

discovered uric acid, and found it in all the cal-

culi he examined, as well as in all the urine. 

BEBGMANN soon afterwards discovered lime in 

certain concretions. In 1797 WOLLASTON pub-

ished his discovery of three calculi in addition to 

those described by SCHELLE—viz., the fusible, 

mulberry, and the bone-earth—and demonstrated 

the chemical composition of these calculi. A few 

years afterwards FOURNOX and VAUGOLSANN 

announced the presence of urate of ammonia and 

calcsia in urinary concretions. Dr. WELLASTON, in 

1810, discovered cystic oxide as an urinary cal-

culus. Dr. MARCEY published an able work on 

urinary concretions in 1817; and Dr. FRUET fur-

ished, in 1821, more extended and exact views 

as to their formation and treatment on this subject. 

Since this period the works of Mr. WILSON, of Sir 

B. C. BHOIDE, of Mr. CROSS of Norwich, of Dr. 

T. THOMSON, of Dr. CUMIN, of Dr. OWEN RIES, 

of Dr. BENJ. JONES, of Mr. COOLEY, and oth-

ers have been published on the subject of cal-

culi.
more recent publications of Dr. Prout, have
carried the pathology and treatment of urinary
crystals to their present very high position
in practical medicine and surgery.

123. A. The form of urinary crystals is gen-
erally more or less globular or ovoid, especially
after remaining long in the bladder. Renal cal-
culi are, however, often of an irregular form,
owing to their being moulded in the pelvis of the
kidney, &c., or are branched like a coralline.
Sometimes those found in the ureter are cylindrical.
When two or more calculi exist in the bladder
they often present a polyhedral or an irregular
shape, from one or more of their sides being flat-
tened, either by attrition or by diminished concen-
tric deposition on these sides. When the calculi
formed in the kidneys and passed into the bladder
are irregular or branched, the shape of the nuclei
which they constitute is not altogether removed
by the successive deposits formed around them in
the bladder. When a portion of a calculus is
embraced by a fold of the mucous membrane, or
suspended between the muscular fasciculi or coats
of the bladder, the part exposed to the urine
increases by successive deposits, so that the sus-
cilled portion ultimately appears to form a pedi-
cle to the entire calculus. (Coulson.)

124. B. The size and weight of urinary concre-
tions are most various—ranging from a few grains
to many ounces. Earle mentions one weighing
forty-four ounces; Lister, one of fifty-one ounces;
and Morand, one weighing six pounds three
ounces! The concretion described by Earle
measured sixteen inches in circumference. The
number of calculi co-existing in the bladder or in
the kidneys is often very various. Most frequently
vesical calculi are solitary; but two or even more
are not uncommon. They are often numerous in
one or both kidneys; but generally not equally so
in both. From ten to twenty or even thirty in
both are not uncommon. An equally great number
are very rarely found in the bladder; although it
is stated that fifty-nine small calculi were found in
the bladder of Buffon.

125. C. The surface of calculi also varies in its
color and characters. The color passes from
white through pale yellow to brown, brownish-
green, and even almost to black. Phosphatic
calculi are often white; those of uric acid vary
from yellow to brown; those of xanthic oxide
have a cinnamon brown tint; while calculi of
oxalate of lime vary from yellow to yellowish-
white, brownish-green, or even blackish-green.
The surface is either smooth and even polished, or
covered with minute crystals, or more or less
rough, and even tuberculated, as in the mulberry
calculus.

126. D. The internal structure or section of a
calculus is either uniform, or formed of concentric
layers surrounding the nucleus; and, in addition
to the concentric lines indicating the separation of
the layers, other lines, radiating from the nucleus
to the periphery, are observed in many of the con-
cretions. In some the concentric layers are easily
separable, in others very firmly adherent, es-
specially when the layers are indicated only by very
faint lines, as in the oxalate of lime calculus.

127. E. The chemical composition of the nucleus,
and of the concentric layers or deposits, may be
the same; or that of the superimposed strata may
differ from the nucleus, or each of the strata may
be different. The constituents are first those which
form entire calculi or layers, in a nearly pure state,
and secondly those which contain, associated with
these constituents, small quantities of other sub-
stances.

128. First Class. — 1. Uric acid. — 2. Uric or
oxide, or cystine. — 5. Ammoniacal-magnesian
phate of lime, and phosphate of magnesia and am-
monia.

129. Second Class. — Those concretions which,
with the foregoing, contain the following in small
matter, fat, extractive, albumen, vesical mucous,
blood. In addition to these, oxalate of iron, benzoate
of ammonia, phosphate of iron, urea, oxalate of
ammonia, hydrochlorate of ammonia, in very
minute quantities, are said to have been formed.

130. The following Table, drawn up by Dr.
Bancroft Jones, shows the readiest means of ascer-
taining the composition of urinary calculi:

URINE—Urinary Calculi Described.

2. By Acids.

With hydrochloric acid, soluble: before heat effervesces.

Solution in acid, when neutralized, gives a white precipitate with carbonated alkalies and oxalate of ammonia.

Carbonate of lime. Soluble in dilute acetic acid, with effervescence.

Oxalate of lime. Insoluble in acetic acid. Decomposed by strong sulphuric acid, forming carbonic acid and carbonic oxide.

3. By Alkalis.

Not destroyed by heat.

Solution in acid, when neutralized, gives a white precipitate with carbonated alkalies and oxalate of ammonia.

Phosphate of ammonium and magnesia. With phosphate of lime is very fusible before the blow-pipe.

Solution in acid, with excess of ammonia, gives an amorphous white precipitate.

Mixed phosphates. Easily fusible, without addition, before the blow-pipe.

Solution in acid, with excess of ammonia, gives a white, partly crystalline, partly amorphous precipitate.

Mixed phosphates. Easily fusible, without addition, before the blow-pipe.

131. I. Uric acid calculi.—Uric acid is the most frequent constituent of urinary concretions, either alone or in combination with bases, especially urate of ammonia, &c. Calculi consisting of uric acid only, or containing in addition a small quantity of colouring matter, are more common than those of any other single constituent. Mr. Couleson states the relative number of pure uric acid calculi in the Museum of the College of Surgeons to be one-third of the whole collection. Dr. Prouv estimated the general average of this conception in the several known collections to be nearly 1:6.

The relative proportions of those composed chiefly of uric acid mixed with urate of ammonia, and of urate of ammonia with minute proportions of urate and oxalate of lime and phosphates, are estimated at 1:3:1; and including the calculi in which the nuclei are formed of uric acid, the proportion is about 1:11. The calculi into which uric acid enters in larger or smaller proportions, as one of the constituents, in the Collection of the London College of Surgeons, are as 1 to 1:36 of the whole number. Two chief varieties of this calculus consist—1st, of that in which the uric acid is deposited in more or less distinct concentric layers, the section of the calculus presenting a series of concentric circles of a compact and semi-crystalline structure;—2nd, of that in which the acid forms a mass of crystalline amorphous grains. These varieties, however, often are mixed, or pass into each other. The first of these have a sometimes granular or finely tuberculated, but smooth or polished surface. When broken, the fragments are angular, whose surfaces are fibrous, as if the concretion were composed of crystalline fibres radiating from the centre to the circumference. The fracture is always in the direction of these radiating fibres and of the concentric layers. The second variety, in which no concentric lamellae are seen, consists either of a firm aggregation of crystalline grains presenting a radiated appearance, or of a porous and earthy structure, often more or less loosely cohering. These calculi are less regular than the former, have a rough surface, a granular and un symmetrical fracture, and are most frequent in the kidneys. The nucleus of the laminated variety frequently presents this character. This form of calculus is more liable than the compact laminated variety to spontaneous fracture in the bladder. Calculi sometimes present cracks in the direction of the radiating fibres, probably owing to an unequal density in the deposits.

132. A third variety of uric acid calculus is known as the pisolform, and is very common. It is seldom solitary; many may exist at the same time in the bladder, and some may be voided by the urethra. They are chiefly formed in the kidneys, and are rarely larger than a common bean or large pea. They have irregular angular shapes caused by attrition against each other, are crystalline, laminated near the surface, and often coated with a thin layer of urate of ammonia.

133. The specific gravity of uric acid calculus varies with the density, and is usually from 1:5 to 1:780; but it has been observed in rare instances as low as 1:276. The colour of this calculus varies from pure white to a deep brownish-red; the colouring matter being of the same nature as that of the urine. (§ 18.) Uric acid is insoluble in alcohol and ether; but is soluble in solutions of potash and soda when heated, and in phosphate and bicarbonate of soda, and is precipitated from these by acids. Some of the alkaline carbonates do not dissolve it. Nitric acid dissolves and decomposes it, equal volumes of carbonic acid and nitrogen being evolved. " Sulphuric and hydrochloric acids do not affect it. Uric acid is a feebly acid, but combines with bases, and forms salts with them. The alkaline urates are sparingly soluble, but very much more so than the pure acid."

134. II. Urate of ammonium calculi, unmixed, is rare. In the collection of the College of Surgeons it exists in the proportion only of one in 500, although this substance forms the nucleus of nearly one-third of the whole collection. (Couleson.) Dr. Prouv, in 1829, first fully demonstrated the nature of this concretion, which seldom exceeds an inch in diameter, and is almost peculiar to childhood. It very rarely occurs in an unmixed state after puberty, and its formation is attended by much constitutional irritation. It is flattened, ovoid, smooth, of a brownish-grey or clay-colour, often with a greenish tinge. It is usually compact in structure, earthy and brittle, consisting of thin concentric layers, so closely applied to each other as to appear homogeneous. The laminae are, however, easily separated. Urine.
of ammonia is a common deposit from urine, having an alkaline reaction, carrying with it more or less colouring matter, which gives it a yellow or brown hue. In its pure state it is white, and much more soluble in water than urea acid.

This salt is often associated with oxalate of lime in calculi, the formation of this latter being preceded by a condition of the urine which favours the deposit of urate of ammonia, so that the nucleus may be formed of urate of ammonia, while the surrounding layers are a mixture of these salts. These calculi are sometimes also contain a small quantity of urate of lime. Urate of ammonia is also frequently associated with the earthy phosphates, either as a nucleus or in alternate layers, or mixed in various proportions with the other constituents.

139. iii. Xanthic or urie oxide calculus is so very rare as hardly to deserve notice; only four specimens of it having been found. It may be distinguished by the means stated in the table given above (§ 130). 137. iv. Cystic oxide calculus is also rare. It is a product of the kidneys only, and hence should be called a matter. It has only been found in four out of seven museums. That of the College of Surgeons contains one or two specimens. It is small, round, and yellowish, with a smooth semi-transparent and glistening surface. This substance is generally free from admixture with others; but uric acid sometimes forms the nucleus, and a layer of uric acid has been found surrounding a nucleus of cystic oxide. It is also occasionally associated with ammoniacal-magnesian phosphate, and carbonate of magnesia.

138. v. Oxalate of lime calculus, in an unmixed state, exists in the Museum of the College of Surgeons in the proportion of 1:20; in that of St. Bartholomew's, as 1:15; and in that of Guy's Hospital, as 1:14. When oxalate of lime calculus having nuclei of urate of ammonia are included, the proportion in the Museum of the College of Surgeons is 1:31. If all the calculi be taken in which the oxalate of lime exists in any amount, then the proportion is, according to Dr. Proust, in St. Bartholomew's Hospital, 1:41; in Guy's, 1:4; in Norwich, 1:74; in Manchester, 1:63; in Bristol, 1:31; in Swabin, 1:27; and in Copenhagen, 1:29; the average proportion being 1:41. Oxalate of lime calculus is rarely pure, being associated with urate of ammonia, uric acid, urate and carbonate of lime, colouring matter, and blood. This calculus, long known by the name of Mulberry Calculus from its tuberculated surface and its resemblance to that fruit, has usually a rounded shape, its surface being dark brown, or nearly black. Its internal structure is compact and hard, imperfectly lamellated, the layers forming waving lines, the colour of which is such as to give the surface of its section a resemblance to a section of a piece of quilled oak, varying from white or yellow or yellowish-brown, or dark brownish-green. The tubercles of the surface appear to consist of striated or uric acid. A second variety of the oxalate of lime calculus is crystalline throughout, its surface being studded with crystals of the oxalate in acutely angled octahedra, these being nearly pure oxalate of lime. A third variety consists of small rounded masses, with a smooth, polished surface, known as the

hemp-seed calculi. It is occasionally crystal-like in the centre and laminated towards the surface, but the laminae are so fine as to give the section almost a compact appearance. It is composed of mixed oxalate and phosphate of lime in variable proportions.

139. vi. Phosphate of lime calculus is rare, especially in a state of purity. Two varieties have been described,—"one evidently of renal, the other of vesical origin. Although entire calculi of pure phosphate of lime are uncommon, this substance is often found nearly pure in the lamina of alternation of calcium." Dr. Proust states that calculi of phosphate of lime are in the ratio of 1:32 in St. Bartholomew's Hospital; of 1:29 in Guy's; of 1:132 in Norwich; and of 1:155 in the Bristol hospital. The general proportion of these calculi to others is 1:117. No specimen exists in the Museum of the College of Surgeons, and in some other collections. The calculus considered renal are composed of the neutral phosphate of lime; those considered vesical are more common than the former. Concretions of neutral phosphate of lime are usually pale brown, with a layer found it, and the lamina so slightly differentiated as to be easily separable into concentric crusts. In some, radiating lines are seen perpendicular to the lamina. These calculi contain animal matter which is precipitated from the alkaline urine with the phosphate of lime.

140. vii. Ammoniacal-magnesian phosphate calculus is commonly known as the "triple phosphate." This double salt rarely forms an entire calculus, but is a very common constituent of other calculi, either mixed with phosphate of lime, as in the fusible calculus, or forming layers in alternating calculus. The proportion of calculi consisting of pure phosphate of magnesia and ammonia, in the collection of St. Bartholomew is as 1:129; in Guy's, as 1:49; in the Bristol hospital, 1:218; in Copenhagen, 1:19; in the Museum of the College of Surgeons, 1:200; while the other collections mentioned by Dr. Proust contain no specimen. The general ratio is 1:120. Ammoniacal-magnesian phosphate is a delicate deposit from alkalescent urine, but usually mixed with more or less phosphate of lime. Calculi of this double salt are generally white, unclean, and roughened by the projecting summits of the crystals, which are transparent in the recent state, but opaque and without lustre after being kept for some time. These calculi are either not laminated or imperfectly so, are friable and easily reduced to powder. But occasionally they are hard, compact, and laminated; exhibiting a semi-transparent crystalline fracture, which gives them the aspect of alabaster (Coulson, Op. cit. p. 291).

141. viii. Fusible Calculus.—Calculi known by this name consist of a mixture of phosphate of magnesia and ammonia, with phosphate of lime in very variable proportions, and they form a considerable portion of all collections. In the College of Surgeons they are as 1:123; in St. Bartholomew's, as 1:124; in Guy's, 1:123; in Norwich, as 1:19; in Manchester, 1:81; in Bristol, 1:12; in Swabin, 1:11; and in Copenhagen, as 1:19, according to Proust; the average proportion being 1:12. Fusible calculus are white, grey, or dull yellow; and more friable
than any others, "being sometimes so soft as to whiten the fingers like chalk when handled; these are not laminated. Others have distinct lamellae, with sparkling crystals of triple phosphate between them, which are so slightly adherent as to be readily separated; others, again, are composed of crystals aggregated into a confused mass."

These calculi are usually globular or ovoid, but sometimes very irregular in shape, being occasionally moulded by the cavity in which they are formed. "They often attain a large size, and sometimes fill the whole cavity of the bladder; in this case impressions of the folds of the mucous membrane are visible on the surface, and when two or more in the bladder they take a cubic or tetrahedral form." Excrecescences composed of triple phosphate are sometimes found, resembling pearls. The ammonio-magnesian phosphate is most abundant in those which have a shining crystalline texture, the phosphate of lime in the earthy and amorphous variety. The fusible calculus is found in all parts of the urinary organs, and in large cysts, or in cavities in the prostate gland. According to Mr. Taylor the earthy phosphates are rarely succeeded by any other deposit; the only exceptions being one in the College of Surgeons, in which layers of mixed phosphates exist in an oxalate of lime calculus, and one in St. Bartholomew's Hospital, in which a fusible calculus is surrounded by a layer of uric acid. These two ingredients of fusible calculi seem to have a distinct origin; the ammonio-magnesian phosphate being derived from the urine, while the phosphate, with a small proportion of carbonate of lime, is secreted together with mucus by the irritated mucous membrane. This is shown in calculi formed around a foreign body introduced into the bladder. This body is first incrusted with phosphate and carbonate of lime, derived, it is believed, obliquely from the mucous surface of the bladder; and subsequently, the irritation being extended to the kidneys, the urine becomes alkaline, and ammonio-magnesian phosphate is deposited; the layers near the nucleus containing more phosphate of lime than those near the surface of the calculus. As a secondary deposit the mixed phosphates are very common, few calculi remaining for a long period of ammonia without being incrusted by them. The uric acid calculus is least subject to this incrustation. These calculi commonly contain urate of ammonia and animal matter in considerable proportion, together with carbonate and urate of lime and uric acid.

142. ix. Carbonate of lime calculi, associated only with a little animal matter, is very rare in the human subject, but common in herbivorous animals, usually mixed in these with carbonate of magnesia. Carbonate of lime is, however, often found in variable proportion in the oxalate of lime and phosphatic calculus. BRIGANTIELLI, Prout, and Smith have described the carbonate of lime calculus. They are always small, the largest not exceeding the size of a large almond; are white or grey, but sometimes yellow, brown, or reddish, and the surface is dusted over with a white powder. They show no concentric lamina, but irregular waved lines similar to those in the mixed calculi. They are not so hard, but remarkably hard, and capable of receiving a high polish. Others passed by the urethra of a rounded and flattened form are compact, lamellar, and light brown. "No specimens of this calculus exist in the museums enumerated by Dr. Prout, nor in that of the College of Surgeons." "Mr. Smith describes eighteen removed from the bladder of a young man; and BRIGANTIELLI forty-eight from a similar source, and sixteen, the size of a nut, from a woman."

143. x. Alternating calculi form a very large proportion of those formed in the human urinary apparatus. This alternation of the constituents in the layers of the same calculus is manifestly owing to successive changes in the urinary secretion, depending upon varying states of the constitution and vital and assimilative power. Alternating calculi consist of a series of alternating layers, differing in chemical composition. Some are composed of two layers, a nucleus of uric acid being covered by a deposit of urate of ammonia, or of oxalate of lime, or phosphosphate of lime, or mixed phosphates. The nucleus may be oxalate of lime, followed by uric acid, or urate of ammonia. Other nuclei of the urinary organs, or oxalate of lime, or mixed phosphates. "Other calculi have three differently constituted layers; thus, a nucleus of uric acid may have deposits of oxalate of lime and mixed phosphates, or oxalate of lime and uric acid; or a nucleus of oxalate of lime, covered by uric acid and urate of ammonia; or a nucleus of mixed phosphates followed by phosphate of lime and mixed phosphates. Others, again, consist of four or even more layers: thus, a nucleus of uric acid incrusted by urate of ammonia, uric acid, and urate of ammonia; or oxalate of lime, followed by uric acid, oxalate of lime, phosphate of lime, &c." (Op. Cit. 296.)

144. The proportion of alternating calculi, of two layers differing in chemical constitution, appears from several sources to average 1:52. The proportion of calculus consisting of three alternations is 1:81; and of those of four alternations in the Norwich collection is 1:209.

The order in which different deposits succeed each other in calculus has been examined by Dr. Proun, with the view of elucidating the changes in the economy upon which this order depends. He found, that the frequency of alternation of uric acid and oxalate of lime is nearly equal; that oxalate of lime far prevails over ammonia; that oxalate of lime is much more frequent than uric acid; that the general ratio in which phosphates succeed other deposits in all the collections is 1:44; and that a decided deposition of the mixed phosphates in calculus is not followed by other deposits.

145. xi. Fibrinous calculus was first described by Dr. Marrey. It is stated by Dr. Proun to be usually of an amber colour and waxy consistence, with more or less of a fibrous texture. As to the chemical tests for this and the other calculus described above I must refer the reader to the table given above from Dr. Bence Jones (§ 130.); and to the chapter on "The Chemistry of Urinary Concretions," in Mr. Cousin's able work already referred to.

146. VI. Causes of Urinary Calculi — The causes of urinary concretions may be inferred from what I have stated above with reference to the pathological conditions occurring the several forms of urinary stones, the concretions taking place in different parts of the urinary apparatus being merely early deposits in those situations of the same constituents as are precipitated by the
urine after being discharged from the body. Whether the concretions are formed within the body, or the deposits take place after the urine is evacuated from the body, many, indeed most of their causes, are the same; the states of the urine which produce them arising chiefly from (c), age and habits of life; (d), from climate, locality, and race; (e), from diet and regimen; (f), from morbid digestion and assimilation; (g), from pathological states of the kidneys, and from the metamorphosis of tissues and of blood globules, in connection (f), with constitutional and vital conditions. But it may be asked, whereabouts should concretions form within the urinary organs, consisting of the same or nearly the same constituents as are deposited from the evacuated and cold urine? To this question the chief answer must be that which I have stated above (see §§ 80—4), namely, that low states of vital power favour the more rapid evolution of that portion of vital emanation which all secretions (the urine as well) possess for a shorter or longer period after secretion according to the amount of vitality endowing the secreting organs, in connection with the extent of change in the constitution of the secretions, with their accumulation and retention, and with the amount of heat dissipated and animal heat retained by them, or furnished to them, during their retention. Although these causes of urinary deposit and concretion have been above considered with reference to the deposits found after the urine is evacuated, certain topics connected with them, more especially with the formation of calculi, require a more particular notice than they have yet received.

147. Deposits from the urine, more or less abundant after evacuation, may proceed for a very long time without any deposit taking place within any part of the urinary apparatus. This immunity from the formation of calculi may arise either from the circumstance of the urine having not been saturated with the substance or substances which usually pass into calculi, or from the states of vital power being unfavourable to the formation of renal vesical concretions, or from the absence of other causes, which favour such formations.

148. i. Age and sex.—The liability of children to calculi has been remarked from the days of Hippocrates; and Mr. Coulson quotes the "Methode de Physiek," in which the author, Philipp Barrow, remarks that "stones in the bladder do endanger oftener in children than in elder folk." (Dib. iii. c. 41. editio quinta, 1617.) Although the liability of strong and well-fed children may not be greater than that of any other class of subjects, yet there is no doubt of weakly, unhealthy, and ill-fed infants and children being more frequently affected with gravel and calculi than older persons. Of 478 operations for stones in the Norwich hospital during a period of forty-four years, 227 were in children under fourteen years. According to Dr. Proctor, the following is the relative frequency of urinary calculi at different ages:—Under 10 years of age, 500;—from 10 to 20, 12;—from 20 to 30, 104;—from 30 to 40, 94;—from 60 to 70, 97; and from 70 to 80, 12. Taking into consideration the numbers of those living at the most advanced ages, urinary concretions are more frequent at these ages than in the prime of life.*

149. Females, notwithstanding their more sedentary habits, and their liability to retain their urine for long periods, are less frequently subject to calculi than males. This is partly owing to their temperate and abstemious habits, and partly to the facility with which a small calculus may escape from the female bladder soon after its descent from the kidneys, and before its retention in the bladder has enabled it to acquire a great size by successive depositions around it. The female urethra, admitting of greater dilatation, and being less complex than the male urethra, and otherwise differently connected and circumstanced, allows the spontaneous passage of calculi which would be retained in the male bladder, and could be removed only by an operation.

150. ii. Habits of living.—Sedentary habits, and luxurious feeding, are more or less influential, according as they may be associated with other causes, in occasioning urinary concretions. The former impairs very remarkably the functions of the skin, and prevents that amount of blood-depuration which these functions effect; the latter furnishes the pabulum, or source, from which urinary concretions and gravel with destitute of the fat in these habits exist in, or are conjoined with, a gouty diathesis, the occurrence of gravel or calculus is often observed; and much more remarkably when a meat diet and malt liquors are very liberally indulged in; for this diet, especially the more nitrogeneous kinds, forms urea and the urates in great abundance, and generates either gout, or gravel, or calculi, or both, and subjects the kidneys to a much greater amount of depurating function by increasing the quantity of morbid materials which require removal from the blood.

151. When the skin ceases to discharge its share of this process of blood-depuration, an increased demand is made upon the kidneys, and an increased supply of the constituents of urinary deposit is furnished to these organs. It will thus appear very manifest that, as the same causes as are more or less concerned in the production of gravel and calculus are also productive of gout, these two diseases must be frequently associated in the same person. The association of calculus with rheumatism is much less frequent than with gout; but when it occurs it may be imputed in great measure to a similar combination of causes.

152. iii. Climate, locality, and race.—Very considerably influence the occurrence of urinary concretions. It is very difficult in many instances to explain the operation of these; but there is no doubt of these maladies being more frequent in humid, temperate, and changeable climates, than in very warm or very cold countries; in some localities more than in others even of the same country; and in the whites than the dark races. Holland, France, England, Germany, have been regarded as furnishing the greatest number of calculous cases; but other countries are by no means exempt.

* M. Civiale, in his "Treatise on Calculous Affections," states that of 8,376 cases, 2,416 were children, 2,167 adults, and 793 old persons. He says that 1,265 occurred before the age of ten, 543 from ten to twenty, 400 from twenty to thirty, 330 from thirty to forty, 291 from forty to fifty, 313 from fifty to sixty, 327 from sixty to seventy, 166 from seventy to eighty, and 17 after eighty. Instances of calculus have been recorded from birth, and very soon after birth. Mr. Coulson operated for stone on a child of eighteen months, and upon a man of eighty years of age.
URINE — URINARY CALCULI, CAUSES OF. 1227

ept from them. Within the tropics, urinary concretions are more rarely observed than in temperate countries, and chiefly, or only, in the very young and ill-fed. The marked infrequency of these concretions in the dark races is chiefly to be imputed to the very small proportion of animal food constituting the diet of these races, especially within the tropics, and to the greater activity of their cutaneous functions.*

The imputed infrequency of calculi in very cold countries is accounted for with much difficulty, especially as animal food is generally freely used. The active employments followed by the natives of these countries, a fish diet adopted by many, and other unascertained influences, may combine to produce this partial immunity. The greater prevalence of calculous diseases in Norfolk than in any other county in England is fully admitted. Mr. Gross, the eminent surgeon of Norwich, considered this prevalence to be owing to a combination of causes — the variables of the climate of Norfolk, to the prevalence of north-east winds, and more especially to the frequency of dyspepsia and acidity in the stomach, and to the consequent superabundance of uric acid in the urine. Sommering states that calculous and gouty affections are unknown, or most rare, in the seaports and towns bordering on the Rhine; the water imparts this immunity to the Rhenish wines, which contain a considerable quantity of the bitartrate of potash. This salt, he contends, changes in the progress of digestion to the carbonate of potash, and acts the part of an alkali.

153. It was formerly believed that the waters of a locality had some influence in producing urinary concretions. This opinion has, however, been controverted by several modern writers; and it is undetermined whether or not the waters which abound in calcarceous or other mineral substances have any effect in producing urinary calculi. The subject has not been investigated with precision, and the arguments on both sides are loose, and indeterminate as to facts.

154. It has been contended by Mr. Copland Hutchison and Sir G. Ballingall, that sailors and soldiers are almost exempt from urinary concretions. But, when it is considered that both sailors and soldiers of those times in which these concretions are seldom observed, the extent of this exception cannot be great. Whatever it may be, the activity of the digestive assimilating and depurating functions in these classes and at their periods of life evidently constitutes its chief cause.

155. iv. Diet and regimen has more influence on the frequency of calculous diseases than is generally believed. The evil produced by animal food used in excess — and many use it in excess relatively to the amount of exercise taken — has been already adverted to (§ 150.) . Highly nitrogenised animal diet furnishes a rich and an abundant chyle, which, during its circulation in the blood through the several viscera, becomes oxidised and otherwise changed, and, in various states of metamorphosis, under the influence of vital energy, originates the most important parts of those materials which require a continued elimination from the blood; and if this be not attained by the active discharge of the several depurating functions — by the kidneys, skin, mucous surfaces, &c.; and if it be not promoted by exercise, sufficient for its fulfilment, an accumulation of these materials in the blood takes place, and, becoming more and more highly animalised and morbid, and irritating by their retention and accumulation, occasions serious diseases, amongst which Gout (as shown in that article, §§ 33—42.) and urinary concretions are the most common.

156. v. Metamorphosis and waste of tissues, &c. — It will be seen, from what has been stated above (§§ 41—5.), that Baron Lemberg and Dr. Goldberg Brav have attributed the solid materials dissolved in the urine, with their deposits and concretions, to the chemical combinations of the elements resulting from the metamorphosis and waste of the tissues in the course of the regeneration and nutrition of these tissues. But if we take into consideration the great amount of these materials discharged into the urine, and refer them only to the sources from which these writers derive them, it must follow that these tissues ought to be renewed several times every successive year of existence! It must be admitted that the metamorphosis and waste of the tissues — to which would add similar changes in the red globules of the blood also — furnish some part of these materials; but a much greater share is supplied by the food, by the chyle conveyed into and circulating with the blood, and by the successive changes therein produced, under the influence of vitality; the regeneration and nutrition of the tissues requiring only a small but appropriate portion of the constituents thus supplied, the less appropriate materials being eliminated from the circulation by the kidneys, skin, and other appendages and other depurations in which these concretions are seldom observed, the extent of this exemption cannot be great. Whatever it may be, the activity of the digestive assimilating and depurating functions in these classes and at their periods of life evidently constitutes its chief cause.

* Dr. Gross (On the Diseases and Injuries of the Urinary Bladder, &c., 2nd Philadelphia, 1851) confirms the rare occurrence of urinary calculi in the coloured races. In ten years he never met with an instance of gravel or of stone in a coloured person. Dr. Dickey in Kentucky, who has the largest practice there, never consulted on gravel or on stones in more than two or three persons, who are constantly exposed to hard labour, and fare often upon the poorest food. Dr. Gross states that urinary calculi are rare in Canada, in Texas, Mexico, and California, that in the United States a larger number of chills and fevers occur in the rocky, Ohio, Tennessee, and Alabama than in any other part; and that the inhabitants of Missouri, Iowa, Wisconsin, Michigan, Indiana, New York, and New Jersey are comparatively exempt.
life are so reduced by the insufficient nourishment as to imperfectly digest and assimilate what is taken, and the blood is thereby diminished in quantity and impaired in quality.

159. *Constitutional and vital conditions* manifestly combine with the preceding causes in occasioning concretions in the urinary apparatus. These conditions I have viewed above (§§ 45, 157,) as consisting of more or less manifest impairment, not only of the digestive and assimilating and depurate functions, but also of the vital endowment throughout the frame. This general impairment of vital power accounts for the prevalence of urinary concretions in delicate and in imperfectly or improperly fed children, or previously to puberty, and in the aged, and for the comparative rarity of these concretions in persons during the prime of life, or during the period of sexual activity, and in those who are neither over-fed or under-fed, and who are not exposed to the remote causes above mentioned.

Bodies or substances introduced or passed into any portion of the urinary apparatus are liable to become the nuclei, around which urinary concretions are more and increase by successive loads on the tissue. Numerous instances of bodies having passed into the bladder, and become the nuclei of large calculi, are recorded by medical writers. To these it is unnecessary to refer, as they are sufficiently known; but they satisfactorily prove that these bodies give rise to the first act of deposition or crystalline formation by the urine, when more or less loaded or saturated with the constituents of urinary deposit and concretion.

160. *Morbid states of some part of the urinary passages* may be attended by an extravastration of a minute quantity of blood, or by a purulent or mucous discharge, which, either in the uniruneous tubes, or in the pelvis of the kidney, or in the bladder, may become the cause of deposit, by attracting the uric acid, the urates or other saline constituents of the urine, and form the nucleus of successive deposits. It is not improbable that a change, such as I have just stated, may take place in some portion of the kidney, or even in some of the arteries of the body, to which it is exposed, or to other causes, and, by favouring the formation of the superabundant saline constituents, or uric acid in the urine, thus form the nucleus of a renal calculus, which may either remain long in the kidney, and increase slowly, or pass into the bladder, and become, as in the case of a foreign body, the centre around which successive and large deposits collect. Most calculous concretions are thus formed, their nuclei and earlier deposits being formed in the kidneys, their chief increase taking place in the bladder.

161. *Inferences.*—The efficient causes of urinary calculi may doubtless operate differently in different diatheses and constitutions, and in different circumstances; more especially in determining the nature of the deposit; but there is some reason for concluding, — 1st. That a diet composed chiefly, or of a large proportion of animal food, tends to increase the oxalate of the uric acid and urates, and to favour their deposition, and to lessen the generation and deposition of the phosphates; — 2nd. That rancid and aceseptic ingesta, and rich sauces, exert nearly similar influences to the foregoing; — 3rd. That whatever promotes the functions of the skin, tends to prevent the depositation of uric acid, and to favour that of the phosphates; — and 4th. That idleness and indigestion tend to increase the depositation of uric acid and to lessen that of the phosphates, both by producing stagnation and the primus vitia, and by impairing the functions of the skin and liver.

162. x. *The Origin and Growth of urinary calculi* was first clearly stated by VAN SWIJNEN (Comm. in Aph. Boerh. 1414.) He remarks, that “stones proceed from elementary principles, which, in a state of solution, previously existed in the humours, and when these meet with an indissoluble basis, they fix themselves thereto, and form a calaxis, which continually increases in bulk from the application of fresh calculi matter.” This statement is probably correct as far as it goes, but various topics connected with the original nature and primary formation of urinary concretions are not comprised in it. DR. GOLING BIRD and others contended for an oxalic diathesis, which gives rise to the secretion of oxalic acid and oxalates from the uric acid and urates existing in the blood. DR. OWEN REES has opposed this doctrine, and has argued that the oxalic acid and its compounds do not produced from uric acid or from urates already existing in the system, but that the change is effected in the urine, after its secretion by the kidney. “In this latter case the uric acid in combination will be secreted as such into the urine, but by after processes, occurring either in the urinary passages, bladder, or chamber vessels, it will present itself converted into a compound of the oxalic acid.” If this be really the case, then we must admit that the state of system in which we observe a tendency to the formation of oxalate of lime in the urine must be considered identical with that accompanying the uric acid diathesis, and as requiring the same treatment, and the same precautionary measures.

163. DR. ALDRIDGE of Dublin has shown the manner in which uric acid and its compounds become decomposed into an oxalic salt. “He has proved that uric acid may be theoretically considered as representing the elements of oxalate and carbonate of ammonia, hydrocyanic and formic acids, if we may suppose oxygen added to the urine, either to external injury, or to other causes, and, by favouring the formation of the superabundant saline constituents, or uric acid in the urine, thus form the nucleus of a renal calculus, which may either remain long in the kidney, and increase slowly, or pass into the bladder, and become, as in the case of a foreign body, the centre around which successive and large deposits collect. Most calculous concretions are thus formed, their nuclei and earlier deposits being formed in the kidneys, their chief increase taking place in the bladder.

164. a. *The chemical reasoning.* DR. O. REES remarks, which shows how unlikely it is that oxalate of lime should exist in the blood, is quite borne out by pathological conditions. He therefore concludes, in opposition to DR. GARRARD and G. BIRD, that, whenever oxalate of lime is found in the urine, it should be regarded as produced after secretion, and that there is no such thing as an oxalic diathesis. LEHMANN, who has al-o opposed the opinions of the late Dr. BIRD, has stated that morning urine, left to stand some hours, is charged with oxalate of lime, and that large quantity, when the fresh urine did not contain any trace of it. WOERER and FRERICHs found that the urates when injected into the blood produced oxalate of lime in the urine. DR. O. REES thus regards oxalate of lime merely as uric acid, or urate altered after secretion,” and that the latter
calciuli contained in museums will show that the uric acid diathesis produces nearly the whole of the calciuli, and in the great majority, especially by forming the nuclei of most of those which are formed of other constituents.

165. The greatly increased quantity, and the insolubility of uric acid, are quite sufficient causes of the deposit of it in the kidneys, especially when in crystals and in the renal sediment, and not at all to be noticed (§§ 167, 169.), without calling in the aid of any other agency. If the deposition of the uric acid in the calculous form in the kidneys, where it originally takes place in the great majority of cases, if not in all, and if the calculus, having passed into the bladder, “fail to produce any great irritation of the vesical mucous membrane, then it will be enlarged by the continued deposition of uric acid layers; but if, as is generally the case, this calculus irritate the surfaces, then the bladder becomes inflamed, and the mucous membrane throws out an alkaline fluid, which now decomposes the ammoniacal salt contained in the urine and liberates the ammonia. This may unite to a portion of uric acid, forming urate of ammonia, so that the next layers of the calculus may consist either entirely of urate of ammonia, or of that salt admixed with uric acid. The changes may cease here, and the calculus, though it increase under these conditions, be thus compounded merely of two constituents. The next change may, however, occur, and may determine the formation of a more compound form of concretion; and this will consist in the pouring out of an excessive quantity of alkaline secretion by the inflamed mucous surface. This will not only completely neutralise the acidity of the urine, but cause—like all alkaline solutions—a precipitation of the earthy phosphates.” (Op. cit. p. 28.)

These will coat the calculus, intermixing or not with the urate of ammonia, or uric acid, according to the amount of secretion and its alkaline character.

166. 8. In respect of the Phosphatic Deposits and Concretions, Dr. O. Renn further contends for their production uniformly from irritation or disease of the urinary mucous surfaces, and for the presence of uric acid or some other form of concretion being a sufficient cause for the formation of phosphatic layers on a calculus. In answer to the questions as to how phosphatic calculi are formed when no other calculous matter can be detected as a nucleus, and what were the conditions antecedent to the phosphatic deposit in such cases, he states that these calculi are rarely met with, and when present are the consequences of disease of the mucous membrane of the bladder, and where, of necessity, the alkaline secretion consequent upon irritation of this membrane is poured out from it in quantity. “This state of things often follows upon enlargement of the prostate with stricture, so that the bladder is not easily emptied.” The retained portions of urine will have their earthy phosphates precipitated by the alkaline secretion of the diseased mucous membrane, and the formation of a calculous result. Hence it follows,—1st., that the presence of other calculous matters, by irritating the bladder, causes a deposition of the earthy phosphates, these matters forming the nuclei of the bladder; and where, 2nd., that the alkaline secretion from the irritated urinary mucous membrane occasions a concretion, independently of such nuclei, by precipitating the phosphates. It was long since remarked by Dr. Payr, that these salts, when present, were always found covering other deposits, and rarely alternating with them; so that, if the nucleus were phosphatic, the crust would be the same, and no covering be found of any other form of calculous matter.

167. Since uric acid is the nucleus of the great majority of calciuli, the conditions under which this deposit occurs should be considered. In persons subject to the continued excretion of uric acid and the urates, the quantities discharged may be very great, without showing any tendency in these substances to concrete into the calculous form. These materials may even give rise, from their abundance, to attacks of “gravel,” without any considerable calculus being formed, and very common means may give relief. In other cases, the deposits in evacuated urine may be in far less proportion, and yet the tendency to concrete into calculi be very early apparent. These facts, as Dr. O. Renn contends, seem to prove that, in order to produce a calculus, some condition must be present besides that which we recognise in a tendency to the deposit of solid matter from the urine. It is necessary to bear in mind what has been said above (§ 169.) respecting the chemical effect of the alkaline secretion from the inflamed urinary mucous membrane, upon which he places more stress than the proofs may be supposed to warrant. But besides possessing the imputed chemical qualities, Dr. O. Renn infers that the secretion from the inflamed membrane evinces mechanical conditions which must influence the result where a tendency exists to deposit solid matters from the urine, and that the secretion from the inflamed mucous surface, being of a tenacious character and containing fragments of epithelium and mucous corpuscles, will cause the particles constituting the deposit to unite and form a nucleus or concretion of successive deposits.

168. Instead, therefore, of viewing the earthy phosphates as secreted by the mucous membrane, Dr. O. Renn believes that this membrane acts merely through its alkaline secretion, which precipitates the earthy phosphates from the urine; and he further infers, that the same conditions noticed with regard to the bladder are present also in the kidneys, and that it is to these conditions in those latter organs, rather than to what exists in the bladder, that we ought to look for the chief cause of the formation of nuclei, and the very general origin of calciuli in the kidneys. “At any rate this would appear to apply so far as the production of a nucleus is concerned.” The mechanical conditions presented by the pelvis and urinary tubules certainly are far more favourable to the agglutination of deposits, than those observed in the bladder; for these are smaller conduits and cavities, and in the immediate vicinity of the tubules the first deposited matters are brought in intimate contact with the spheroidal epithelium, which under irritation rapidly desquamates and is more especially liable to entangle floating particles of deposit, and so to favour the formation of calculi. “The reasoning,” Dr. O. Renn adds, “I have used with the phosphates are but the found with full force to the formation and growth of calculi in the kidney. From what I have now
URINE.—SyMptoms OF CALCULI IN THE KidNEYS.

adduced, I would submit, that if we except cases in which are formed of the four following rare substances, viz., cystine, carbonate of lime, silicic acid, and uric oxide, we may consider all calculous disease as originating in the gouty or uric acid diathesis.** (Op. cit. p. 38.)

168. A nucleus may form in any part of the urinary canals; but the tubules are by far the most frequent seat of the original deposit. Small particles are sometimes found in the secreting structure; and if these do not pass onwards to the tubular structure, they may increase by deposit of successive layers until a calculus of considerable size is produced. In this case a portion of the organ, corresponding to the development of the concretion, may be destroyed, and symptoms varying with circumstances be produced. The first deposit may, however, pass lower down into the tubular structure, or thence into the pelvis of the kidney, and either remain in either of these situations or pass along the ureter into the bladder, causing more or less distress, in some cases extreme suffering, during its passage; and having reached the bladder, it may be expelled through the urethra by the stream of water, or remain in the bladder and become the nucleus of a large concretion.

170. VII. Symptoms of Urinary Calculi.—In the Kidneys.—The symptoms produced by a calculus or calculi in the kidney vary with the size, form, or smoothness of the stone, its situation in the organ, and the constitution, temperament, and diathesis of the patient. The calculus may remain in the kidney, or even several may remain, or pass thence into the ureter or bladder. If it remains, either relief of more or less severe symptoms may take place after a time, owing to a cystic covering forming over it, or disorganisation of the kidney sooner or later supervenes and destroys the patient. If the calculus remain in the kidney and become encysted, more or less severe pains in the loins or in one or both sides, often extending down the thigh or thighla, and sometimes upwards under the shoulder blade, colicky pains in the abdomen, nausea, vomiting, haematuria, and frequent calls to pass the urine, are complained of. These symptoms may gradually subside, and they may recur alternately every few weeks during the urine periods and were of various degrees of severity, especially after sudden or severe exertion, particularly when the trunk of the body has experienced a shock or concussion. The pain often becomes dull or aching, or is seated chiefly on one side of the abdomen, or extends to the groin, or a sym pathetic pain, resembling neuralgia, is experienced at a distance from the region of the kidney, and not infrequently extends to the testicle of the affected side. After a lengthened period, and after frequent recurrences of the symptoms in slighter grades, the patient either experiences an immunity from further suffering, or complains only of slight and wandering or recurring pains, which often may be traced to one or other kidney.

171. In less favourable cases of retention of the calculus or calculi in the kidney, the symptoms assume the features described when treating of Inflammation of the Kidney (§§ 48, 49, 59, et pluris), and of Pyelitis (Ann. Kinnaird, §§ 174—183. 192—198, et pluris), and are fully described, with the several relations of this subject, in the article, and more especially at the places now referred to. I may, however, remark at this place, the difficulty of diagnosis between a calculus in the right kidney and the passage of gall stones. At the commencement of the irritation produced by a calculus in the right kidney, and when the symptoms are very severe, or when a calculus has entered the ureter from the pelvis, the complaint may readily be mistaken for gall stones, especially when the vomitings, pain, and spasm are very urgent, and if all the symptoms be not carefully examined. I have found it even recently very difficult to determine at first as to the seat of disease; and this difficulty is increased if there be, as there frequently is, pre-existing disorder of the biliary functions, more especially interruptions of the biliary secretion, or some degree of jaundice. As the symptoms of renal calculi proceed, and especially as the calculi pass into or along the ureter, the nature of the complaint becomes more manifest, and indeed is most frequently so from the commencement, especially when the symptoms attending the secretion of urine are well marked, and blood-globules are observed in the urine. When the haematuria is very considerable, especially after exertion or sudden movement of the trunk, in connection with the other symptoms of calculous nephritis (see Kinnaird, §§ 48 et seq.), the nature of the case is evident; and if the draining of blood continues for a considerable time, and the local symptoms are very acute, the oxalate of lime calculus is not infrequently the cause.

172. II. The Diagnosis of renal calculus is rendered most difficult in the gouty and rheumatic diathesis, and in cases of chronic disease of the urinary bladder and prostate gland; for the pain in one or both sides of the lumbar region may be rheumatic or gouty, or may proceed from chronic nephritis, or Bronzy's disease, or from pyelitis or abscess of the kidney, occurring either primarily or caused by calculus or following chronic ure-cystitis or stone in the bladder, or even from inflammation or abscess of the lumbar muscles. If any tumour or swelling be detected in the region of the kidneys, the antecedent symptoms should be duly estimated, and the examination directed to the existence of collections of matter in the urine, or to their distention by urine from obstruction of the ureter, or to the presence of malignant disease of the kidney. Of these several states of disease, as well as of the passage of a calculus along the ureter, no correct diagnosis can be formed until the urine be tested, and the results considered with due reference to the quantity, specific gravity, appearances, deposits, and quality of this secretion; the ability of retaining it, to the frequency of the calls to void it, and to the particular alterations of sensibility complained of in the regions of the kidneys, ureters, bladder, and urethra, as well as in the testes, abdomen, and lower extremities, and to the states of constitution and of vital power. In the course of renal disease associated with calculi, the symptoms are so varied, and manifest in numerous combinations, with the seat, duration, extension and associations of morbid action, that descriptions applicable to all cases would be hopeless; but it is clear that irritation existing in one part of the urinary apparatus will extend to, and more or less affect the whole; that although the symptoms will be present chiefly in the situations just indicated, they may extend
URINE—SYMPTOMS OF

still further; and that a correct examination of the urine will indicate with more or less accuracy the nature of the affection, especially when viewed in connection with the local and constitutional symptoms, the difficulty of forming a diagnosis between the disorders which result from renal calculi and those which most nearly resemble them will altogether disappear. In this subject I must refer the reader to what I have stated respecting the inflammatory and organic diseases of the kidneys and urinary bladder, and the complications which they present in practice.

173. iii. The symptoms indicating the passage of a calculus from the kidney to the bladder may be so slight, especially when the calculus is small and smooth, as to occasion but little inconvenience and to excite no anxiety or even the attention; and it may remain long afterwards in the bladder without the patient being aware of its presence. But if the renal calculus be large, or rough, more especially if it be an oxalate, its passage along the ureter is attended by the most excruciating suffering. The pain is seated more especially in the loins, generally of one side, extends from the course of the ureter and down the thigh, the chord to the testes; and is attended by retching, vomiting, and by intermitting colicky or abdominal pains. The patient is bent double, or to one side, rolls about, and is in the greatest agony. In the less severe cases there are rigors, nausea, restlessness, pain in the back, stretching in the course of the ureter to the bladder, thigh, and testicle, often with its retraction, coldness of the extremities, and prostration. The descent of the calculus commonly occupies from 12 to 24 or 36 hours. The calculus may become impacted in the vesical orifice of the ureter; the flow of urine from the corresponding kidney may then be prevented; dilatation of the ureter, and distension of the tubular structure of the kidney will ensue, terminating in absorption of its secreting surface; but most of the usual symptoms of stone in the bladder will be absent.

174. iv. The symptoms of a calculus in the bladder are well known, and require at this place but few remarks. But in tracing back the history of these cases, and when inquiring into their existing states, the facts should not be overlooked,—1st, that stones in the bladder originate in the great majority of cases, in a calculus formed in the kidney, which, having passed into the bladder, forms the nucleus of further deposit and concretion in this organ; — 2nd, that the formation of the calculus in the kidney, and its passage thence along the ureter into the bladder, must have been attended by more or less aliment referable to these situations; — 3rd, that a calculus very rarely or never originates in the bladder without previous disease either of this viscous, or of the prostate gland, or of the urethra.

175. The symptoms chiefly characterising the existence of a concretion in the bladder are frequent calls to micturate, pain at the end of the penis, hematuria, especially after exercise, and pain with or without hematuria on a jolting motion or succession of the trunk. If these, however, be alone recognised, they may mislead the physician; for they may all be present, and yet a calculus may not be the cause. Hence the necessity of inquiring into the history of the case, and of duly estimating the early symptoms. For some malignant growth may exist in the bladder and occasion all the symptoms just mentioned.

A calculus in the vesical cavity generally falls behind the prostate, but it slits according to the posture of the patient. In the earlier stages of vesical calculus, the viscous being yet healthy, a dull pain, with a sense of weight about the neck of the bladder, or un easiness, extends to the hypogastric region, perineum, groins, or thighs. If the stone be smooth, the symptoms commence and advance so slightly and slowly as to excite but little attention and no anxiety; but sooner or later, either from the size of the calculus or the irritation produced by it, the features of the affection become manifest. The bladder is irritable and cannot contain its contents; the calls to micturate are more frequent; and the expulsion of the last drops is attended by pain, shooting along the perineum and penis, and centering in the glans. Sometimes when the urine is flowing in a full stream, it is suddenly stopped, as if by some body falling into and obstructing the orifice of the bladder.

Exercise, sudden movements, and the jolting of a carriage occasion great suffering, and even a discharge of bloody urine, which in plethoric or other habits of body may be of considerable extent or continuance; as the disease continues, and the bladder becomes more affected, micturation becomes more and more frequent and distressing. Patients often grind their teeth with agony; and the last drops of urine are expelled with spasm of the bladder which endures for some time. The urine and contents of the vesicula seminales are sometimes passed involuntarily, and increase the distress and exhaustion of the patient. There is occasionally pruritis, with or without sexual desire.

176. I need not further describe the symptoms of vesical calculus, but merely briefly advert to the importance of recognising some of the complications of this malady, and which may either precede it, or follow it, more especially the latter. Of these the most important is disease of the kidney or kidneys. This may have preceded the vesical calculus, and been associated with, or caused by, the formation of the renal calculus, which formed the nucleus for further deposit and concretion when it passed into the bladder. But in this state of complication the renal disorder is generally slight, or even hardly exists when the calculus has reached the bladder. If, however, it be arrested in its course, more particularly at the vesical extremity of the ureter, the renal complication may be most severe and dangerous. After the calculus has been long in the bladder and superinduced much disease in this viscous, the interruptions in the way of urinary excretion, the extension of irritation along the ureters, and other circumstances, often develop serious disease, and even extensive disorganization of the kidneys. In some cases, also, the irritation of the bladder by a calculus may superinduce prolapse of the bladder in children or even in older subjects, and hemorrhoids in the latter class.

177. v. Diagnosis. The symptoms described above (§§ 174—6), generally lead to the important measure of ascertaining, beyond a doubt, the existence of a stone in the bladder, viz. sounding. The calculus may be palpated if it is large, and may be often attended by most of the symptoms characterising vesical calculus, and the fact of this
URINE—TREATMENT OF URINARY CONCRETIONS.

operation, which is so requisite in the latter case, is being often most injurious in the former, should lead us to pause before it is resorted to, and the states and appearances of the urine very minutely examined. In cases of vesical calculus the urine generally contains more or less of the ordinary sediment and organic matter, and the blood discharged with the urine is generally in smaller quantity than in malignant growths in the kidneys or bladder.

178. In calculus, hematuria generally follows upon some unwonted exertion. In malignant growths in the bladder or kidneys, the tendency to nausea and vomitings is greater, and there are more marked appearances of cachexia and of anemia than in calculus. In some cases, also, a careful examination of the abdomen will lead to the detection of tumors, if there be malignant disease of the kidneys, especially after the bowels have been freely evacuated. Malignant disease of the kidneys or bladder, or fungoid growths in the latter, especially when far advanced, is characterized by discharge of urine, with much blood, intermixed with which the cells constituting malignant disease may be detected by the aid of the microscope. Dr. Owen Rees repels much confidence in the evidence furnished by these cells, of the existence of such disease. He describes them to be "of variable size, the smaller being about four times the diameter of a blood corpuscle, the larger twice that size, or even of greater diameter. They are colourless and more transparent than the white corpuscles of the blood, and contain within them matter of varying size. These nuclei differ in number in each cell. Sometimes one only is present; sometimes four or five. Though there would appear a general tendency on the part of these bodies to assume the circular form, they are for the most part of irregular outline. Sometimes a mass of them may be seen agglutinated together, and then they are more or less square, or they may approach to the hexagonal form." Dr. O. Rees states that he has never seen corpuscles like these in the urine, except in cases of malignant disease. Where these are found, he contends that the sound should not be put into the bladder, as it may be followed by excessive, or even fatal hemorrhage, a case of this latter issue having fallen under his observation.

179. VIII. TREATMENT OF URINARY CONCRETIONS. I. Of calculi in the kidneys. When the symptoms indicating the existence of calculus in the kidney are severe, and the patient is strong or plentory or not reduced by hemorrhages from these organs, then cupping over the loins, followed by warm baths and fomentations, will afford relief. The preparations of soap and extract of henbane, or of belladonna, may be prescribed internally, whilst mucilaginous or demulcent fluids, containing the carbonates of the alkalies with narcotics, should be freely administered. The bowels ought to be kept open by means of olive oil, in frequent doses; or by the citrate of potash taken freely, in a state of effervescence, and with the addition of a few grains of the acetate of lead with opium, or the spirits of terepine, cautiously exhibited in small doses, episthems of the same being applied to the loins, will be found of service; or the gallic or tannin acid, &c. may be prescribed. In cases where it might be injurious to abstract blood, dry-cupping over the loins may be employed.

180. Having removed the more severe symptoms by these or similar means, a course of medicines calculated to prevent the formation of uric acid and urates, and to lessen their irritating effects, should be entered upon. But such a course will prove ineffective if the diet and regimen of the patient be neglected. The citrate and bichromate of potash, the citrate or carbonate of magnesia, and other antacids, conjoined with tinctures, will generally be of service, both in preventing acidity and promoting digestion, and in depurating the blood. A vegetable and demulcent diet should be adopted, the quantity of flesh-meats much diminished, and the white kinds of fish, boiled only, and with no other sauce than a squeeze of lemon, should replace a large portion of the other articles of animal food usually taken. The beverage of the patient may consist of any of the mineral waters in which the alkalies are most abounded; or distilled water may be drunk, when effervescing with the bichromate of potash and citric acid or lemon juice, or with the addition of either the citrate of potash or citrate of magnesia, according to the state of the bowels. When the bladder is irritable, the several kinds of soap, with henbane, or with opium, may be taken at bedtime. In all these cases, I have seen much benefit result from the use of distilled water, as the vehicle for depurants of the blood, and for the important domestic purposes of making tea, coffee, &c. The due promotion of the functions of the skin in this case of patients, and the use of the warm bath, of flannels next to the skin, should not be overlooked.

181. ii. The Treatment of the passage of renal calculi is often of urgent importance, owing rather to the agony produced than to the danger incurred. The sufferings of the patient are generally increased in these cases by constant or frequent retchings, which also require to be assuaged. A warm bath should be immediately ordered, and before it is ready, or while it is being prepared, from 40 to 50 minims of laudanum, or a less dose of Batley's solution of opium, may be given. If the symptoms should continue after the patient's removal from the warm bath, creasote may be prescribed with demulcents, or other substances; or hydrocyanic acid, or chloroform, may also be added to these. The warm bath may be repeated, or warm fomentations be employed, and emollient and mucilaginous fluids, containing alkaline carbonates, and snodynes be freely taken. If the patient's sufferings be not very considerably relieved by these, the extract or tincture of belladonna may be added to the pills or mixtures already advised, and to the fomentations, which should be continued until complete relief is obtained.

182. During the passage of calculus from the kidneys the state of the urine should be carefully ascertained, and the bowels satisfactorily evacimated, either by magnesia or the citrate of magnesia in the form of enemata, or by elixir or elycon, as prescribed in large quantity, and repeated as they may be required. After relief is obtained, the medical treatment advised for renal calculi should be practiced in for some time conformably with the indications furnished by the appearances and deposits of the urine. The diet
and regimen recommended above (§ 180.) should be continued throughout, or modified according as the state of the patient and the alterations in the urine may suggest, due care being taken not to reduce the digestive and the assimilative functions to lower vital or constitutional power, and not to impair the secreting and depurating actions.

183. The treatment of vesical calculi differs but little from that advised. The avoidance of exertion or of sudden movements, &c., as advised for renal disease, strict attention to diet, and the adoption of the medical treatment recommended for the several kinds of urinary deposit, conformably with the kind existing in the urine, and for renal concretions, are also required for vesical calculi. In many cases, however, the irritation produced in the bladder, the consequent inflammation, hsematuria, &c., and the complication of disease of the kidneys, of the prostate, &c., render the treatment most difficult, and its benefits often doubtful, however rationally conducted. It is unnecessary to add at this place to what I have already stated when describing the treatment of diseases of the Urinary Deposits and of the Kidneys, and when noticing the indications of cure furnished by Urinary Deposits. When a stone exists in the bladder and produces irritation of more or less manifest severity, the probability of that irritation being followed by the consequences just named, however judicious the medical treatment may be, is very great; and hence the necessity of removing the stone by a surgical operation, unless the consecutive diseases or lesions,—the superinduced complications, forbid its performance. As to this and other topics connected with the surgical treatment of vesical concretions, I must refer the reader to the very able surgical works enumerated in the subjohed Bibliography and References.

184. IX. Diseased Excretion and Suppression of Urine.—The urine may be voided not only in the very different degrees of quantity, and in the states of chemical constitution described above as indicating and important venal function, and of local disease, but it also may be discharged with more or less effort and suffering on the part of the patient. It may, moreover, be retained in the bladder, owing either to paralysis and over-distension of the organ, or to mechanical obstacles at the neck or outlet of the viscus, or in some part of the urethra. The urine is also often either secreted in remarkably small quantity, or suppressed altogether, owing to disease of the kidneys, the blood and nervous masses becoming poisoned by the arrest of the important depurative function of these organs, and by the resulting excremental plethora of the vascular system, and accumulation of urea, &c., which these organs eliminate from the blood as long as these functions continue. An altered or poisoned state of the blood may also arrest the functions of the kidneys.

185. ii. Difficult or retention of urine, urine difficultis excretio, or Dysuria (from difficult, difficult, and opeor, urine), is entirely symptomatic of disease affecting some part of the urinary apparatus, or some organ or part in the vicinity. It is generally characterised by heat and pain, as well as difficulty in delay in passing the discharge. Dysuria may depend upon the properties or chemical constitution of the urine, especially in irritable states of the urinary bladder and urethra; and, in such cases, as well as in others where these properties are not present, it may be symptomatic of disease of the kidneys, especially of inflammatory and organic diseases. More particularly, however, it is a symptom of the diseases of the urinary bladder, and of the urethra, and of gravel and urinary concretions. It is not infrequently present in diseases of the neck and body of the uterus, in the severe cases of dysmenorrhea and leucorrhoea; in dysentery and inflammation of the rectum, and in cases of inflammatory hemorrhoids.

186. ii. Strangury, stranguria (from στραγγίων, to squeeze, and ὅψω, urine), is a more severe degree of the preceding complaint, and is most frequently a symptom of diseases of the urinary organs, more particularly of over-distension of the bladder, of lesions of the neck of the organ and prostate gland, and of the urethra, and of urinary calculi and gravel. In dysuria the urine may flow in a full stream; but in strangury it is much interrupted or passes in small quantities, or in drops, after great effort.

187. iii. Icheria (Ιχθεία, I arrest, and ὅψω, the urine) has usually implied, an arrested discharge of urine; the arrest taking place either in the kidneys—icheria renalis; anuria (Wills), renal ischuria; or in the bladder, from paralysis of the organ, or from some obstruction at its outlet—icheria vesicales, I. vera, I. retentionis, vesical ischuria; or in the urethra—ischuria urethralis, from stricture, phymosis, &c. Besides those symptomatic states of ischuria, or of retention and suppression of urine, other forms of retention arising from calculi, and from disease of, or tumours in, the uterus or vagins, &c., may be enumerated. This subject is more fully discussed in the article Symptomatology (see §§ 210—218); but there is one part of it, and that of the highest importance, which requires a more particular consideration, namely, icheria Renalis, Anuria, of Dr. Willis, or Suppression of Urine, the excretion not being eliminated by the kidneys, urine not being secreted and exchanged.
cachectic inflammation of the Malphigian bodies, but most generally in a partial or incomplete form. Suppression of urine is a more complete or rapidly dangerous or fatal form; often follows injuries and diseases of the spinal cord or its membranes, and is generally accompanied by the death of other disassembling result; any disease which, as a consequence of misplaced or suppressed gut, may be ascribed to a state of congestive inflammation of the secretion structure of the kidneys, in which the organic nervous or vital influence of these organs is rapidly exhausted or suppressed.

194. A. The symptoms caused by suppression of urines vary with the circumstances of the case, and more especially with the slowness or rapidity with which suppression takes place, and with the disease of which it is a consequence. — A. When this condition proceeds from granular lesions, atrophy, or other organic change in the kidneys, it is generally slow in its progress, and it is often not observed, or rather the diminished excretion of urine has been of considerable continuance, before it has attracted notice; the urine being not only very scanty, but also very much altered from the healthy state, however, the symptoms, such as hematuria and diseases of the kidneys, and in the preceding sections. In these cases, with the slow progress of diminution of urine and of the solid constituents of this excretion, the cutaneous and pulmonary exhalations are sometimes increased, and their odour is most offensive; effusion often gradually supervenes in the cellular tissue and in the shut cavities, sometimes with evidence of a chronic inflammatory irritation of the serous membranes investing these cavities; and ultimately the dangerous and commonly fatal phenomena rapidly supervening upon the acute form of suppression, or of that occurring in the advanced stage of malignant maladies, make their appearance.

190. B. When suppression of urine takes place more rapidly, the disease is then characterised by many of the symptoms of continued fever. There are pains in the back, but chiefly in the head and in the lower extremities, with nausea and vomiting, and often with a sense of weight or of uneasiness if actual pain or severe aching in these situations be not felt. In some cases vomitings are urgent, and the fluid thrown up is generally watery, and in a few instances has an urinous odour. The pulse is rapid, full, and dis tended; perspiration, at first scanty, becomes more copious, in some instances abundantly so, and ultimately it has often an offensive urinous odour. After a time varying from three to five days, or occasionally longer, effusion takes place in the cellular tissue and shut cavities, with a tumid or bloated state of the countenance, especially about the eyes. In cases of somewhat longer duration, oedema of the face and extremities comes on and advances more slowly; but as these changes advance, sopor supervenes and passes into profound coma, and sometimes into coma terminating in convulsions, especially in children. Generally long before the death of the patient the diminution of the quantity of urine, or its entire suppression, has been recognised by the physician, if he have been consulted so early; and when the catheter is introduced to determine correctly the existence of urine in the bladder, — the presence or absence of which, however, is generally evident by the state of the hypogastric region, — nothing beyond a very minute portion of a thick, muddy, or mucous and offensive urine is withdrawn. This form of suppression of urine, whether occurring primarily, as I believe I have seen it in a very few instances, or in the early progress of other disassembling result; any disease which, as a consequence of misplaced or suppressed gut, may be ascribed to a state of congestive inflammation of the secretion structure of the kidneys, in which the organic nervous or vital influence of these organs is rapidly exhausted or suppressed.

191. C. When suppression of urine, or anuria, occurs in the advanced progress of malignant or pestilential maladies, the duration of the symptoms more especially appertaining to it is much shorter, and the course of the malady in which it appears is very much hastened by it to a fatal issue. The changes usually consequent upon the anuria often do not take place until shortly before death; the earlier effects of the lost function of the kidneys being chiefly an aggravation of all the symptoms and diagnostic characters of the malady in which it occurs. It is very remarkable in the case of malignant scarlet fever and pestilential choleras and yellow fevers, as well as in the more specific forms of it, such as in a day or two, and often after a few hours, as in pestilential choleras, sinking, sopor, convulsions or coma, &c., occur and terminate life; oedema of the face and extremities, effusion within the cranium, &c., also taking place shortly before death in scarlet fever, and sometimes in the hemorrhagic pestilence. In pestilential cholera, the watery discharges from the stomach and bowels prevent the excremental plethora of the vascular system from taking place, that occasions the coma, effusion, &c., which are usually the results of anuria, when it supervenes in the course of other acute maladies.

192. D. Drs. Willis and Schönlein described a form of anuria which sometimes occurs in weak and cachectic children, and which I have observed also in the children of the poor living in cold, damp, or low situations. In these there is a dry and waxy surface of the mucous surface is much disordered; the secretions and excretions are acid and offensive, and the cutaneous surface is affected by various eruptions, chiefly erythematous, vesicular, and pustular. The urine is scanty, is sometimes more or less albuminous, is voided in drops after short intervals, with pain and difficulty, and is ultimately quite suppressed. The pulse is at first quick and weak, but it gradually becomes slower, as sopor, coma, or convulsions supervene. These symptoms are usually preceded by constipation, by oedema of the face and extremities, by vomiting and retellings, and are ultimately followed by death. In some cases, especially when perspirations are abundant towards the close of the disease, this excretion has an urinous or an acid and offensive odour. The breath also often has a similar odour. 193. E. In fatal cases of rapid or sudden suppression of urine, and when this event occurs in exanthemous and malignant diseases, the kidneys are found to be extremely dilated, and notwithstanding the diminution of the quantity of urine, or its entire suppression, has been recognised by the physician, if he have been consulted so early; and when the catheter is introduced to determine correctly the existence of urine in the bladder, — the presence or absence of which, however, is generally evident by the state of the hypogastric region, — nothing beyond a very minute portion of a thick, muddy, or mucous and offensive urine is withdrawn. This form of suppression of urine, whether occurring primarily, as I believe I have seen it in a very few instances, or in the early progress of other disassembling result; any disease which, as a consequence of misplaced or suppressed gut, may be ascribed to a state of congestive inflammation of the secretion structure of the kidneys, in which the organic nervous or vital influence of these organs is rapidly exhausted or suppressed.
If the vomiting preclude the retention of these medicines, a very small quantity (\(0.5\) or 1 minims) of cresote may be added, or from three to six drops of nitreta opii, to each dose, or both may be given in addition, and the terebinthinated embrocation applied over the epigastrium. When suppression of urine follows chronic disease of the kidneys, compliances, and dropsy, and more especially when it is associated also with some disease of the heart, then little or no permanent benefit will be derived from any means of treatment; those just mentioned being the most appropriate, and sometimes affording temporary benefit.

BIBLIOGRAPHY.

Fever (see § 66). In the slower or more chronic cases, the appearances are altogether the same as those stated when treating of granular or echecitic inflammation of the kidneys (§ 59. et seq.). The changes in the cases of suppression of urine in children, which I have had an opportunity of observing, were similar to those which I have mentioned under scarlet fever. Indeed, in some of these cases I had viewed the disease as an abortion or latent state of scarlet fever, in which the affection of the throat and skin had not appeared, as I have described it in that article. (See § 26. et seq.)

194. It is manifest that the fatal result, in cases of suppression of urine, arises from two pathological conditions:—1st, from the excremenitious plethora of the vascular system, the superabundance of the watery element causing effusion on the brain, its membranes, cellular tissues, and sub cavities; and 2nd, from the accumulation of urea, uric acid, &c., in the blood, which poisons the nervous masses and vital structures, thereby aiding the destructive effects of effusion, or even proving fatal independently of these effects.

195. F. The treatment of suppression of urine is rarely encouraging, owing to its want of success, and the fatal results which usually follow the very general failure of it. Yet treatment should not be neglected, as it may succeed in a few or rare cases. Besides, hopes of success may be reasonably entertained, if the suppression is incomplete. In cases occurring in acne, exanthematic, malignant or pestilential maladies, the small quantity of urine passed before complete suppression takes place may or may not be albuminous, and of diminished specific gravity; it is sometimes thus altered in scarlet fever, but it is not, as far as I have seen, in other malignant diseases. In these, if the state of the pulse and other circumstances allow, the patient should be cuffed on the loins, and the operation repeated, to an extent according to the features of the case and the effect produced. If the loss of blood cannot be hazarded, dry-cupping should be adopted; and the patient, under all circumstances, should be placed in a warm bed, carefully rendered more or less alkaline by the addition of the carbonate of potassa or soda. After leaving the bath, a turpentine emulsion or embrocation may be placed over the loins, or an embrocation consisting of equal parts of the compound turpentine and camphor liniments should be applied in the same situation, or over the abdomen. The bowels must be kept freely open by the more diuretic purgatives, and by terebinthinate or other enemata; and diuretics should be taken, variously combined, or conjoined with sedatives or anodynes, according to circumstances, more especially the preparations of taxacum, of digitations, &c.; the carbonates, the nitrates; the acetates, the tartrates, the bitartrates, and the bis-borates of the fixed alkalies, in large doses, or in as large as the stomach will tolerate. If these fail, the following may be tried as a dernier ressort:—

URCUTARIA—Description of.

Classif. — Order Genus (Willan) 117.

Class. 1. Order (Author). 1. Definite. — A fibrile, non-infectious exanthem, characterized by an eruption of prominent wheals or spots, paler or redder, or even both, than the surrounding surface, rarely of long continuance, often recurring or being aggravated in fits, and always attended by a burning and stinging sensation.

2. I. Description. — Dr. Willan has enumerated six species of Urticaria. — 1st, Urticaria febrilis; — 2nd, Urt. eruviisa; — 3rd, Urt. perstans; — 4th, Urt. Conferta; — 5th, Urt. Subcutanea; and 6th, Urt. tuberosa. These have been accurately arranged by J. Ravey under two heads, according as their course is acute or chronic.

3. i. Urticaria Acuta. — The first variety under this head is the Urt. febrile, which is generally caused by the ingestion of various articles, and frequently by shell-fish (see §§ 427. et seq.); and is to be imputed rather to a peculiar susceptibility or idiosyncrasy of the individual than to any noxious or poisonous quality in the article occasioning the eruption. Commonly in an hour or two after the ingestion of the article causing this affection the patient complains of a weight at the epigastrum, nausea, sinking, or giddiness. These are followed by fibrile symptoms, by heat of skin, and by the appearance of an eruption on the shoulders, breast, loins, the inner sides of the arms, thighs, &c., generally consisting of reddish or whitish elevated spots, surrounded by bright crimson areoles. The spots are generally irregular, but sometimes circular, varying in size, and elevated above the surrounding surface. When numerous in any part they are often confluent, the skin presenting a red tint, and being stiff and swollen (Urt. Conferta). The eruption is attended by distressing itching, pricking, or stinging, especially during the night; and sometimes the confluent variation is associated with purpuric or hemorrhagic blisters. When this form of the disease...
by shell-fish, or by poisonous ingesta (§§ 427, 434,) the eruption is sometimes preceded or attended by vomiting or purging, or by both; and spasms, sensations of constriction, convulsions, and sinkings, &c. have even supervened, and in rare instances terminated fatally. In the slighter cases of urticaria, caused by the ingesta, the white itching elevations of the skin are not observed; a simple efflorescence, resembling scarlatina, and belonging rather to erythema than to urticaria, being the characteristic symptom. After twenty, thirty, four, thirty-six, or forty hours the eruption usually declines, and soon afterwards leaves only slight traces on the skin, which are effaced in a few days.

4. Febrile urticaria sometimes appears without any appreciable cause, excepting teething in children, and intense moral emotions in adults. The symptoms are nearly the same as those caused by the ingesta, excepting that vomiting and purging are not observed, that the febrile symptoms continue longer, usually a week or longer, and that the eruption is less general, but appears and disappears in almost all parts of the surface, preceded by slight febrile symptoms. The patient can often excise spots of urticaria by friction; but these generally disappear in a few hours. In some instances the rash continues for two or three weeks (Urticaria purpura, Willan) and is attended by anoxia, functional disorders of the digestive organs, febrile symptoms, general depression, malaise, &c. The eruption usually declines imperceptibly, but it often returns with itching in different parts, and it last disappears. When urticaria has been severe, or has continued long, a slight desquamation generally follows.

5. i. Urticaria Chronicus.—Chronic urticaria often lasts for months. M. Rayer states that he has known it continue for several years. This form of the disease is most frequent in females, and in persons with a delicate or sensitive skin. Although most common in those who complain of disorder of the digestive functions, yet it sometimes occurs in persons who are otherwise in good health. The eruption appears at irregular intervals, sometimes in one place, at other times in another (Urt. evanida, Willan), without fever, and often for a few hours only. The patches are generally irregular, and closely resemble the wheals produced by flagellation. They have no erythematous areola, and are attended only by severe pruritus. In some cases, instead of itching, a stinging or prickling sensation under the eruption is experienced (Urt. Subcutanea, Willan). In these the eruption is scanty, consisting of a few red points, but little elevated above the surface, and a small number of spots, that appear at very remote intervals. M. Rayer considers this form of urticaria to be very uncommon, and to be caused by violent moral emotions.

6. A severer variety of netter rash sometimes appears (Urt. netter, Willan). It consists not merely in slightly prominent elevations, but in true tuberocities of various sizes, which are hard, deep-seated, extending to the subjacent cellular tissue, attended by slight ecchymosis, and by a tense and sore state of the limbs. These tuberocities appear usually in the evening or at night, with itching and stinging, and disappear before morning, leaving the patient weak, restless, and depressed. They occur more particularly on the loins and extremities; but they may come out over the whole of the body, causing swelling of the neck, limbs, and even the face; and are attended by various symptoms, convulsions, faintness of the heart, &c. They are usually developed with febrile action, and subside with the remission of the fever, reappearing with its accession (Febris intermittens Urticata, Franke).

7. The varieties of chronic urticaria are very irregular in their courses. They sometimes disappear for several days, and are followed by an appreciable cause, or appear without any appreciable cause, after uncertain intervals. They often are not entirely removed for many months, in rare instances, not for some years; and either spontaneously or by a methodical plan of cure. Turner, Hedeman, Rayer, and others, mention cases which continued many years. I have recently attended a case with Mr. Pettigrew, which resisted for above a year the most active treatment. When the eruption of these chronic forms of the disease is very severe, it is followed by a bran-like desquamation, constitutional symptoms of varied character, and a severity being present, or recurring irregularly.

8. The Associations of Urticaria are common, and often important. With constitutional disturbance and disorder of the digestive organs, often depending upon an improper regimen and diet, urticaria is very generally associated. J. Frank saw it complicated with quinacrine and tertian agues at Pavia, in May and June, 1794; and at Wets, in March and April, 1812, in so many cases as to appear epidemic. In acute rheumatism the wheals of urticaria may appear, although not so frequently as the efflorescence of erythema or rosacea. Nettter rash is uncommon in connection with diseases of the respiratory organs or passages. It is sometimes observed during various chronic visceral diseases, or cancerous and organic maladies; and after miscarriages occurring in nervous females. Urticaria may be complicated with other cutaneous eruptions, especially with erythema, or with rosacea, or with lichen, and occasionally with impetigo. Whichmann saw it associated with variola; Hufeland with measles; Rayer with purgation; and I have seen it in a case of jaundice, and in another of semile purgation.
URTICARIA — TREATMENT OF.

chiefly to the general use of olive oil in the former, and of animal oils and rancid substances, and dried meats and fish in the latter country. Nettles rash is most common in summer, especially in women, and persons of a nervous and sanguinous temperament. It is more frequent in children, the young, and adults, than in the aged. Cold, or rather exposure to the air, appears to have considerable influence on the development of the wheals of urticaria, especially in respect of certain parts of the surface which are usually covered.

10. iii. Diagnosis.—It should not be overlooked that the leaves of the urtica urens, urtica dioica, and rhus toxicodendron, the bite of the common bug, of the gut, of the flea, and the hairs of certain caterpillars, may occasion an eruption of wheals which, although evanescent, may at first, if the cause be not inquired after, be mistaken for urticaria. The white and raised wheals surrounded by areola, characterising urticaria, differ from patches of erythema in these respects, and in stinging, pricking, and itching. Erythema nodosum is distinguished from urticaria lichenosa by the persistence of the extravasation and the intermitting course of the latter. Rhus alopecuroides cannot be confounded with the wheals of urticaria, as it presents red spots and patches, and not the dull white spots of urticaria, and is not attended by pruritus, and the pricking or stinging of this latter. The history and all the phenomena of the case will prevent the eruption from being, at any time during its course, mistaken for either measles or scarlatina. The papules of Lichen Urticatus are much more likely to be mistaken for urticaria; but they are less extensive and less prominent than the spots of urticaria; their colour is deeper, they are harder, and they never disappear spontaneously. The bites of insects already mentioned, although causing wheals and itchings, cannot be mistaken for any form of urticaria.

11. iv. Prognosis.—This eruption has appeared as a salutary crisis in some instances of internal inflammatory disease, as remarked by Koch, and for others, to have been followed by the development or the increased activity of some internal disease. This has very probably been owing to the occurrence or progress of the latter causing the subsidence of the urticaria, rather than to the suppression of this eruption. No one of the forms of urticaria is attended by any danger, although the chronic states are often accompanied with much distress, and frequently resist the most appropriate treatment for a long time. The acute forms, following the ingestion of poisonous articles, however severe, or even when fatal, cannot have the unfavourable results imputed to the eruption, inasmuch as these results proceed from other changes produced by these causes, the eruption being the least important of their effects.

12. v. Treatment.—When acute urticaria is present the immediate cure is to remove the exciting cause, or by articles which are injurious from the idiosyncrasy of the patient, emetics and the other means advised when treating of those poisonous articles which usually cause this eruption, are required (see Art. Poison, §§ 448, 450.). After the stomach and bowels have been evacuated, liquor ammoniace acetic and nitrate of potash may be given in the camphor mixture, or in any demulcent infusion or decoction; or the hydrochlorate of ammonia in similar vehicles. Subsequently a warm bath may be resorted to and repeated, and the bowels kept open by means of cooling aperients. I have found frequent infusions of hot mint in small doses on the surface of mint water, and the application of this oil to the surface, either before or after a warm bath, of very great service. In full and robust habits of body, or in the young and strong, especially if visceral congestion be present, vascular depletions, in form and amount according to the circumstances of the case, should be early prescribed, a strict diet and regimen enforced, and in all cases a free state of the bowels, by means of cooling aperients, and emollient and demulcent decoctions, be preserved. The insomnies and restlessnessto generally observed in the severer cases of this eruption require opiates, but they should be compounded with cooling diaphoretics and alkalies. I have found James’ powder, or the antimonial powder, with the compound soap-pill, or the compound ipecacuanha powder, or a full dose of the carbuates of the fixed alkalies, or of magnesia, and very successful in mitigating these symptoms, especially when either of these means has been resorted to after due evacuation of the bowels, and when taken early in the night, or rather in the evening. If febrile action be present, saline aperients, the acetate or citrate of potash or soda, with nitrate of potash, and spirits of nitric ether, in mint-water, or in camphor mixture; or the citrate of magnesia, in doses sufficient to act on the bowels, will be found of great service.

13. The chronic states of urticaria are often most difficult to remove; and more especially as they are generally caused by errors in diet, and perpetuated by the use of articles which either disorder the digestive organs, or impair the deputating functions, or otherwise affect the circulating fluids, so as to irritate the capillary vessels of the skin. In these cases patients should adopt a restricted diet and regimen, and avoid spirituous, vinous, and fermented liquors, all kinds of fish, and live entirely on farinaceous and vegetable food. I have seen the most obstinate cases, which had been treated by the too generally prescribed preparations of arsenic, iodine, &c., in large and improperly combined doses, yield to the use, chiefly or entirely, of farinaceous and vegetable diet, and distilled water; the secretions, excrescences, and deputating functions generally being duly promoted by gentle cooling aperients, such as those mentioned above.

14. When the chronic states of urticaria assume a remittent or intermittent form, and if they do not readily yield to the means already advised, then the preparations of cinchona may be given with the carbuates of the fixed alkalies, or with the solution of the acetate of ammonia, or with the addition of the nitrate of potash; and warm alkaline baths, or vapour baths, be resorted to. External applications especially those which are oily or greasy, should be avoided, excepting the olive and almond oils, to which the hydrocyanic acid may be added when the stinging and pricking are distressing. But even these should be washed off in a few hours, before they are made rancid by the air and the cutaneous excitation.
UTERUS. — Some of the diseases of the uterine organs have been considered in the articles on the OVARIA and their diseases, on MENSTRUATION and its disorders, on DISEASES of the ovarium, uterus, and Fallopian tubes, on LEUCRITIS, and on the diseases of the VAGINA and VULVA. Certain uterine maladies have also been fully described with reference to the puerperal states, when treating of Puerperal DISEASES. It now remains for me to view those morbid conditions of the uterus which are not noticed under other heads, and which appear to be of such importance as to require attention.

I. MORBID SENSIBILITY OF THE UTERUS.

CLASSIF. I. CLASS; V. ORDER. (See Preface.)

1. DEVA. — Pain of the uterus, generally very severe, sometimes continued, at other times remittent or intermittent, particularly of the neck of the organ; occurring at all ages, but seldom after the cessation of the catamenia; and not necessarily depending upon very manifest organic disease, although more or less inflammation and alteration of structure frequently exists.

2. Morbid sensibility of the uterus occurs, according to my observation, in two forms: — 1st, in that which has been denominated irritable uterus, when indications of a slow, chronic, and often most protracted state of irritation, amounting in some cases to inflammation and its usual consequences, are present in the os and cervix uteri; and, 2nd, in that which is more nervious, where these indications are not manifest, and where the nervous characters of intermission, &c., are most evident. An approximation of the characters of the one affection to those of the other may, however, be remarked in some instances.

3. Irritable Uterus, or irritability of the uterus, is frequently spoken of by Dr. Goode. The notices taken of it in the works of Riedel, Pouret, Riverius, Stoll, and some others, are extremely unsatisfactory, and even calculated to mislead, it having generally been referred by them to rheumatism or gout affecting the womb. Since the publication of Dr. Goode’s observations on this affection, some manifest improvement has been made in the subject; and the more recent writers on the complaints of females have further illustrated this subject, and shown its connection with chronic inflammatory irritation.

4. Irritable uterus is seldom met with before twenty-three years, and seldom after the menstrual epochs has ceased. Dr. Goode says that it is not attended by change of structure, and that it does not tend to such change, whilst Dr. Dewees states that he has usually found some change about the neck of the uterus. In the case of this affection for which I have been consulted, some have been unattended by any manifest alteration of structure, and others have been accompanied by indications of chronic inflammation of the cervix and os uteri. (§ 21. et seq.) In a case in my own family, no alteration could be detected for a very long time, but a change of structure subsequently became manifest, and assumed a malignant form.

5. ii. SYMPTOMS.—A. The constitutional symptoms are, increased frequency of pulse on the slightest emotion or exertion; sometimes flushes, alternating with chilliness, particularly to the excursions; pain in the lowest part of the abdomen along the brim of the pelvis, and often also in the loins, exacerbated by exercise, whilst it is diminished, although not removed, by perfect quietude and the horizontal posture; the pain sometimes recurs in paroxysms, even when the patient recovers, or is quite still, and is generally increased for a few days either before, or immediately after, menstruation; emaciation, paleness, weakness, and increased sensibility and irritability of the whole frame; an irregular state of the bowels, with difficult or painful micturition, and a pale, white tongue, particularly in the morning. Sometimes the pulse is soft, at other times firmer than usual; and although generally somewhat quickened, it is occasionally not above the usual frequency. The skin is commonly dry, and its temperature sometimes augmented, whilst the hands, legs, and feet, particularly the latter, are cold. The febrile exacerbations seldom terminate in perspiration. The patient occasionally complains of headache, which is often increased towards night. The appetite is usually impaired or capricious; and the bowels either are confined, or much relaxed — most frequently the former, the latter more particularly when acted on by purgatives, which generally excite a paroxysm of pain. The urine is either sparing, high-coloured, and depositing a copious sediment; or it is pale, copious, and limpid, particularly when the affection is complicated with hysteria or neuralgic pains in other parts of the body: it is generally voided with difficulty and pain referred to the urethra; sometimes it is retained for a long period, and passed with great suffering.

6. B. THE LOCAL SYMPTOMS.—If the uterus be examined, it will be found excessively tender, particularly its orifice and neck, the former generally being neither misshapen, nor indurated, although sometimes somewhat swollen — as is the cervix often also participates. When the pain is excited by an examination, or by coitus, which is also very painful, it does not readily subside;
and it is often induced by the patient seating herself suddenly upon a hard chair or bench, and usually by the sexual congress. In addition to these she frequently complains of a throbbing or fluttering sensation in the pelvic cavity and vagina. Walking, riding, or any exercise increases the symptoms, and causes severe lancinating pains through the pelvic cavity, particularly in the course of the urethra, and about the centre of the sacrum; as these subside, a dull, diffused pain is felt in the same direction. Leucorrhoea frequently accompanies this affection, and often becomes abundant, the discharge varying from a thin transparent and inodorous matter to a thick, mucopurulent, and offensive fluid. There is often increased heat of the vagina. The uterus is occasionally found lower in the vagina than natural, and its neck is generally shortened and enlarged, and sensible to the touch. Pain is felt immediately behind the mons veneris and anterior part of the brim of the pelvis. The catamenia are at first but little affected in this complaint, but they ultimately become more and more scanty, whilst the sufferings of the patient are generally increased at their accession. They often prematurely cease, the pain being reduced by the protracted disease and by the confinement.

7. ii. Neurologic Uteri, or uterine neuralgia, has been considered a distinct disorder by some writers, and a modification of irritable uterus by others. (See Neurologic Disorders, § 43.) In this form of altered sensibility of the uterus, the pain is most exquisite, is generally referred to the body of the organ, does not continue for a very long time, and subsides entirely, or nearly entirely. It is altogether paroxysmal, and sometimes almost periodic. The general or constitutional symptoms are less evident, or altogether absent in this affection; but the debility and exhaustion may be greater. Examination per vaginam does not excite the pain in the intervals, although it may aggravate it in the paroxysm; and neither heat, nor leucorrhoeal discharge, is usually present. This form of complaint is not uncommon, on some occasions is aggravated by the causes which occasion or increase the sufferings in irritable uterus. The chief features of the neuralgic disorder are the extreme violence of pain during the paroxysm, and the complete or nearly complete subsidence of it during the intervals. Cases, however, occur in which the symptoms of the one form of disorder appear to lapse into those of the other.

8. C. The diagnosis of morbid sensibility of the uterus is manifest in the severity of the pain, and in the localization of it in the cervix and os uteri, especially of the irritable form of disorder, these parts evincing the utmost tenderness on examination, and the existence of great irritation, and ultimately of chronic inflammation and its consequences, namely excoration, leucorrhoeal discharge, &c. The neuralgic form of disorder, as well as the irritable form, is unattended by any symptoms of micturition or of bowel action. Although both affections are independent of displacement of the uterus, yet they may be accompanied with displacements in one or other form. They cannot be mistaken for dysmenorrhoea or painful menstruation, for they may be present during the intervals between the menstrual periods, although they may be aggravated by the accession of these periods. On vaginal examination of cases of these complaints, the uterus is usually found in its natural position, excepting that it is sometimes situated lower down in the pelvis, or otherwise more or less displaced. In many cases it is free from organic change, beyond slight tumefaction or fulness, and occasionally softness of its mouth and neck; but in prostrated cases, the changes produced by continued irritation and consecutive chronic inflammation usually supervene.

9. D. The prognosis of the above states of morbid sensibility of the uterus is favourable as regards the life of the patient, although it is not so favourable as respects a quick recovery. It may, if the causes continue to operate, be followed, after some years, by organic change, or even by malignant disease of the os and cervix uteri. Whilst most of these cases will recover, if judiciously treated, some can only be relieved, and others may continue to suffer for many years, especially if the secret habits or vices in which the malady has originated, be persisted in. The issue of these cases will depend on the causes inducing them, on their recurrence, and on the physical and moral conditions of the patient.

10. E. Causes — a. The predisposing causes of these states of morbid sensibility of the uterus, are constitutional sensibility and irritability, the nervous and irritable temperaments, the impulsive and susceptible disposition, a spare habit of body, previous liability to painful, difficult, or scanty menstruation; repeated abortions, and masturbations. — b. The exciting causes are not accurately ascertained; but they appear to consist chiefly of fatigue, exertion, prolonged walks, or dancing or standing too long, and falls on the lips or back, or succussions of the body, particularly when the uterus is susceptible, or during the catamenia. Riding on horseback or in a carriage, especially if the road be rough, and during the menstrual period, or without duly evacuating the bladder; the use of cold or astrigent washes or lotions; profuse lochia or leucorrhoea; exposure to malaria, &c.; sitting on damp or cold stones, earth or iron seats, venereal excesses, and self-pollutions; neglected or protracted leucorrhoea.

11. F. The nature of irritable uterus was supposed by Dr. Gowers to be similar to that of painful menstruation, the former being permanent, the latter recurring with the periodic discharge. He further inferred, that it is not inflammatory, because it does not terminate in change of structure; but it may, and often does, terminate in such change. He states that, after repeated examinations, nothing is discovered excepting extreme tenderness and slight swelling, or rather tension of the cervix and os uteri. He further supposes, that the fact of many cases, after having lasted for years, terminating in entire recovery, is a sufficient proof that it is a disease of function only.

Dr. Dewar contends that the womb, the uterus, and its symptoms of micturition or inflammation of the body of the uterus (§§ 53. et seq.) also being absent. Although both affections are independent of displacement of the uterus, yet they may be accompanied with displacements in one or other form. They cannot be mistaken for dysmenorrhoea or painful menstruation, for they may be present...
the views of Dr. Goon, which, however, are much more applicable to the nature of neuralgia of the uterus, than to the irritable form in which morbid sensibility of the os and cervix uteri most frequently occurs in practice. (See Neuralgic Affections, §§ 43, 44.)

12. My experience, derived from many cases in which my opinion has been requested in consultation, leads me to conclude, that the two forms of morbid sensibility of the uterus are characterised by very different pathological conditions: 1st, that neuralgia of the uterus is an affection of the nerves of this organ, induced by depressing and exhausting causes, and is altogether independent of inflammatory action and organic change; although it may be associated with one or other of the several displacements and organic lesions of the womb about to be noticed; 2d, that irritability of the uterus is caused by irritation of the os and cervix uteri, this irritation being attended by e الزوج morbid sensibility and tenderness, and by some degree of inflammatory action; that the irritation supersedes chronic inflammation of these parts, which may be due to organic causes for a very long period, and before it is followed by excoriations, by a morbid secretion and discharge from the everted surfaces, and from the irritated mucous glands in these situations, and ultimately by granulations, ulcerations, and even more serious organic changes. According to this view, the greatest number of the cases formerly termed irritable uteruses, or which had this term appropriately applied to them at an early stage only, were actually instances of irritation followed by chronic inflammation of the os and cervix uteri and its consequences. The writings of Dr. Henry Bennett have fully demonstrated the existence of these lesions, which, although denied by Dr. Robert Lee and some others, have been very often observed by Dr. Simpson, Dr. Tyler Smith, Dr. West, Dr. Whitehead, of Manchester, M. Chomel, and numerous continental writers, and by myself. The imperfect manner in which affections of the os and cervix uteri were observed when Dr. Goon wrote, prevented the true state of these parts from being duly recognised and estimated: and yet his admission of the existence of tenderness, fulness, tension, &c., in this situation, is a sufficient proof of the presence of inflammatory irritation, or of irritation usually passing into inflammation. (See Inflammation of the Os and Cervix Uteri, §§ 21, et seq.) When writing upon this subject in 1829, I remarked that, if morbid sensibility of the os and cervix uteri exist for some time, it often induces, or is attended by, an alteration of the circulation in these parts, by swelling and tension, by great tenderness, and by increased secretion from their surfaces—the augmented secretion generally tending to prevent the disorganising effects of inflammatory irritation or action from taking place.

13. iii. Treatment.—Very different means are requisite for these two forms of morbid sensibility of the uterus, and it is of great importance to note that the one is unconnected with inflammatory action, is purely nervous, and is sudden in its accession and in its subsidence, whilst the other is more or less inflammatory either originally, or consequentially upon irritation, the morbid action, owing to the organ remaining exposed to the repeated attacks, being more or less modified in character, and prolonged in duration. The circumstance of the os and cervix uteri being possessed of sensibility only inferior to that of the clitoris, their erectile organisation, and their abundant supply of mucous follicles, often render them excessively tender and painful when inflamed, or even when they are the seats of irritation, and enable them to furnish an abundant secretion tending to resolve or to diminish inflammatory action, and to prevent the usual consequences of this action. Notwithstanding the advantages these parts derive from their organisation, vital powers, and free discharge from their surfaces, when irritated, inflamed, or otherwise affected, inflammatory action, when once developed in them, is the more disposed to be protracted, but it is, from these circumstances, much less liable to consecutive alterations of structure; the chief organic lesions which occur being superficial excoriations, granulations, and ulcerations, with a more or less abundant leucorrhoeal discharge. These alterations are the more likely to take place when the uterus falls low in the pelvis, when the morbid secretion accumulates, or is retained, in the vagina, when vital or constitutional power is depressed or exhausted, and when the treatment pursued, and other circumstances, permit the air to have access to the irritated or inflamed parts. This form of altered sensibility of the uterus, however severe the pain characterising it, being either identical with, or nearly allied to, irritation or chronic inflammation of the neck of the organ, the treatment appropriate to it will be necessarily the same as advised for that disease: the more painful symptoms being treated by such combinations or modifications of the remedies as have been found most beneficial in neuralgic affections, and in irritable and exhausted states of the system.

14. The Neuralgic Affection, or the nervous form of morbid sensibility, of the womb will, therefore, be chiefly considered at this place; the means, however, to be recommended for it will often be also required in the inflammatory states, and their consequences hereafter to be noticed, either conjointly with other constitutional and local remedies, or after recourse has been had to them. The indications of cure in this affection are, 1st, to subdue the sufferings of the patient, and 2d, to prevent their recurrence, by restoring the constitutional powers, and healthy state of the uterus. Certain of the means calculated to fulfil the first, will often aid the accomplishment of the second intention. The means to be employed with these views are the same as have been fully considered, when discussing the Treatment of Neuralgic Affections (see §§ 60, et seq.); and they may be used as there recommended and prescribed. 15. In the more violent cases, the more energetic sedatives and narcotics may be applied locally, in the form either of suppositories, or of injections thrown into the vagina, or of enemata, the bulk of which should not exceed three or four ounces; or, if overlooked things are to be prescribed, too large a dose of the more sedative substances, especially in the injections, as the effects produced by them when thus exhibited, may be as violent as when taken by the mouth. In a case which I attended with the late Dr. Moore, very marked relief of the pain was obtained by the means of a small piece of sponge, about half a dram of the tincture of belladonna, in a female
The paroxysm generally subsided after a very few minutes, and the more restorative means recommended in the article now referred to were administered. The patient soon recovered, adapting the peculiarities of the case, and more especially with due regard to the states of the vascular system, and to the causes and associations of the complaint. These last, it is most important to recognize; for not only may the disorder be the result of depressing or exhausting causes, but it may be complicated with one or other of the several forms of displacement of the uterus, and even with tumours or other organic changes of the organ.

16. Besides the means now mentioned for the removal of the paroxysm, others may be tried; chloroform taken in doses of from twenty to thirty drops, by the mouth, or injected into the vagina, in the same or somewhat larger quantity; or suppositories in which the extract of belladonna forms an ingredient, may be introduced; or other narcotics may be similarly employed. In the most severe cases vomiting or prostration may occur as a sequel to add to the patient’s distress; for these the oxalate of cerium has been prescribed by my friend Dr. Payton, conformably with the opinion entertained of the salts of cerium. In a case which I attended with Dr. Payton, the oxalate of cerium was suggested by him, in doses of two grains, thrice daily, and gave great relief. Besides these, various means have been recommended to be applied either above the pubis or over the sacrum. Embrocations of turpentine, containing opium or warm epiphanes of turpentine, have often succeeded in giving relief in a short time when thus employed. Aconite or veratrum applied over the sacrum, has been resorted to; a small quantity of the extract or of the tincture of either of these being mixed in an ointment or liniment; but the use of these powerful sedatives requires caution, although externally applied. In some instances, warm narcotic injections, repeated and varied according to circumstances, will be of service. In some instances, warm narcotic injections, repeated and varied according to circumstances, will be of service.

17. If this complaint be dependent upon chronic inflammatory irritation or action, or upon some other lesion of the uterus (§§ 21. et seq.), the means required by such lesion should be adopted in addition to that which may appear most appropriate of the remedies now advised; and the diet and regimen of the patient ought to be regulated with due reference to such associations and to other peculiarities of the case. In the great majority the recumbent posture, varied as may be required, rest, and ease of body and mind, are necessary, and in all strict avoidance of the predisposing and exciting causes, both ascertained and inferred, should be insisted upon. A reference to these causes will show (§§ 10. 22.) that certain of them when once indulged in are not readily relinquished, and that persistence in them will render the most judicious treatment of no avail.

18. The means which are most suitable for the fulfilling of the second intention, viz., the restoration of the general health, and of the healthy state of the sexual organs more especially, are the same for this complaint as for accomplishing the second indication of treatment advised for the several forms of inflammation of the uterus (§§ 108. et seq.). In some instances, in which I viewed neuralgic or very painful affections of the uterus as the result of the influence of malaria, I have during the intervals between the paroxysms, and with the view of restoring the healthy functions, prescribed either the arsenical vermifuge solution in the usual doses, or the preparations of iron with quinine and camphor.

II. Inflammations of the Uterus and Appendages.

Classification—III. Class. V. Order (Author in Preface).

19. Definition—Pain and weight or uneasiness in the hypogastric region, and behind the pubis, often with pain in the lumbar and sacral regions and in the regions of the ovaries, extending to the groins and tops of the thighs, with more or less symptomatic fever, increased towards evening.

20. Inflammations of the uterus present very different phenomena and occasion very different results, according as the morbid action is seated chiefly or entirely in the neck of the organ, or in the body, or in the internal surface, of the uterus, or as it may implicate the peritoneal surface of the fundus. The symptoms vary also with the duration and stage in which they may occur as a cause, either constantly or consecutively, with the nature and extent of the complications, so often presented by inflammation of this viscus; and they vary with the grade of morbid action, and with the manner in which the sensibility and sympathies of the uterus are excited.

21. Inflammation of the Uterus and its Consequences.

—Inflammation of the cervix and os uteri is generally chronic and often very protracted. It is rarely acute unless it be caused by the gonococcal virus, several instances of this form of disease having come before me, one of them at the commencement of my practice, when the possibility of the occurrence was generally denied by the physicians of this country. But this specific form of the disease will be noticed hereafter. When inflammation attacks this part of the uterus it is often slight and insidious in its accession, and, being frequently attended by more or less discharge, is too commonly viewed as a form of leukorrhea, and considered of comparatively slight importance. This circumstance often tends to its neglect at a period when a judicious treatment might have removed the disorder without any difficulty. But, being overlooked or neglected, and perpetuated or aggravated by persistence in the causes which occasioned it, the disease becomes most obstinate and protracted, and is followed by changes of structure which generally render the treatment more or less difficult. In all cases where the local and constitutional symptoms suggest even the idea of disorder or disease of the uterus, the advice given by a most eminent and able physician, M. Chomel, should be followed: "La fréquence et la diversité des affections de l’utérus, la forme latente de beaucoup d’entre elles, l’éloignement qu’éprouvent la plupart des femmes à parler des sensations et des dérangements dont cet organe est le siège, sont autant de motifs pour le médecin de porter de lui-même son attention de ce côté, d’adresser aux femmes les questions relatives à ce sujet, et enfin de ne négliger aucun des moyens d’exploration, toutes les fois que quelconque circonstance en impose la nécessité. L’oubli de ce précepte deviendrait la cause d’erreurs de diagnostic aussi graves que fréquentes."
nately the worst features of our common nature—the most bitter manifestations of the "odium medium," which is generally the most bitter and unendurable of sensations. The success is achieved—have been displayed respecting a recourse to those means which are requisite to "exploration," and the existence of those lesions which are to be ascertained chiefly by the exploration in question—namely, by examinations per vaginam, by means of the senses of touch and sight. On this subject it is quite clear that the post put forth, rather than that the abuse of any particular mode of investigation, or an improper recourse to and employment of it, cannot invalidate the proofs of the great advantages which are derived from its proper and judicious use; and that the evidence and practice of men of character, position, and experience, are not to be impugned or disregarded by others who are not entitled in any point of view to become the censors of their professional brethren.

22. A. The causes of chronic inflammation of the neck and mouth of the uterus and of the cervix are those which have been enumerated as producing the two chief forms of altered sensibility of the organ (§§ 10), more especially difficult or disordered or arrested menstruation, excessive sexual indulgences, and masturbation; falls on the back or hips, or injuries in the vicinity of the pelvis or peritoneum; difficult and instrumental labours and abortions; the extension of inflammatory irritation to the neck of the uterus from the vulva and vagina; gonorrhœal infection; the foul air ascending open privies; the use of pessaries; displacements of the womb; cachectic habits of body, and neglect of cleanliness. In many cases the cause of disorder is either not manifest or can only be inferred. The disease seldom occurs before puberty, or long after the cessation of the menopause. It is most frequently observed from 20 to 50 years of age.

23. B. Symptoms.—The existence of inflammation of the neck and mouth of the uterus is evinced by the appearances of the part; by the local signs and symptoms, and by the sympathetic or constitutional phenomena. The appearances of the cervix and os uteri, it might be supposed could not fail of evincing the existence of inflammation of them, more especially since those appearances have been disclosed by the use of the speculum. Even previously to the use of this instrument, this disease might have been detected by the sense of touch and the phenomena resulting from examinations by this sense, and by the secretions and alterations of sensibility attending it. If the appearances constituting inflammation of these parts are admitted of doubt, and consequently of discussion—although discussion has not in this instance been always the consequence of either doubt or unbelief—surely the several results of inflammation, more especially tumefaction, exudation, and secretion, against those by whom success is achieved not have been misunderstood nor misrepresented. When treating of Leucorrhea in 1841 (published in 1842), I referred the two most important states of this complaint to "inflammatory irritation of the mucous glands of the os and cervix uteri," and to chronic inflammation of the internal os of the uterus, and contended that these forms of Leucorrhea, especially the latter, are not infrequently of a specific inflammatory nature, or gonorrhœal. Of this specific form I have seen several cases, the first of which occurred at the very commencement of my practice (in 1821), the success is achieved in the inflammation having extended to the Fallopian tubes. (See Art. Leucorrhœa, § 19, et seq.)

24. a. The appearances of the cervix and os uteri vary with the severity and character of the inflammation—with the amount of irritation and congestion preceding and attending it; with the intensity of the secretions; with the nature and the amount of exudation and secretions accompanying it; with its extension to the internal surface of the cervix; and with alterations of structure which may have already taken place. The earliest appearances are not always observed; for congestion or irritation, of a more or less inflammatory character, may have existed for a longer or shorter time before the complaint had advanced so far as to induce the patient to have medical advice. When the mucous surface of the cervix is simply congested or inflamed, it usually presents a red or livid tint instead of the pink or pale rose colour of health; it is often dotted with florid papula, or with whitish punctae, according as its mucous glands are inflamed or distended with a muco-puriform matter. Frequently the surface of the cervix is covered with this matter so as to prevent its exact state to be observed until this secretion is removed. At first the cervix is somewhat swollen or enlarged, but still soft; but with the persistence of the inflammatory action, and with the exudation into the structure of the cervix more or less induration is superadded. At this early period the os and cervix uteri are hotter and more tender or even painful to the touch than in the healthy state; but the amount of tenderness and of pain appears to depend more upon the temperament and susceptibility of the patient than upon the severity of the inflammatory action—or rather upon the irritable character of this action; the pain being in some cases, both in this stage and throughout the disease, such as to constitute the irritable uterus of several writers as noticed above (§§ 3. et seq.).

25. b. As the disease becomes more chronic or protracted, the cervix becomes somewhat elongated, and approaches nearer or almost lies upon the posterior part of the vagina. At the same time the os uteri is more open than natural, owing, in some cases, to the congestion, inflammation, or enlargement of the mucous glands at the orifice and internal canal of the neck, externally to the os internum of the uterus, and in others to congestion of its internal mucous surface and subjacent tissues. This inflammatory state of the mouth and canal of the cervix was shown when treating of Leucorrhea (in 1841) to be a frequent cause and form of that complaint, as it is an associated condition of chronic inflammation of the cervix, and it usually presents a dark reddish or livid hue; the mucous pus or muco-puriform matter secreted by the inflamed mucous surfaces of the cervix varies much in appearance and quantity in different cases; but the chief part of this secretion, as I have stated in the article just referred to (§ 19. et seq.), manifestly proceeds from the cervical canal. The character of the state and character of this secretion, especially upon its discharge, depend much upon the time of its retention in the vagina and upon the exclusion or access of air.
26. e. Inflammation in the neck of the uterus may continue a long time without giving rise to its usual results. This may be owing to the partial resolution it may experience from the exudation or secretion from its surface and from the mucous glands, or from the menstrual flux. But after an indefinite time, the mucous membrane of the cervix and os uteri, more especially that portion of it pertaining to the vaginal canal, undergoes further change, generally commencing with encroachments or abrasions of the surface and passing on to ulcerations, but very rarely with loss of substance. These may present minute red granulations, or vegetations of a livid hue. When an abrasion or excoriation is alone present, the surface is generally of a vivid red, and the granulations on its surface are very minute; this state of the lesion occurs chiefly within the mouth and canal of the cervix, and most frequently in single females. In a more decided form of ulceration, the granulations of the ulcerated surface may be formed of a vivid red hue, scarcely bleeding on pressure, or they may be large, fungous, livid, and bleeding readily on a slight touch. Sometimes the granulations or vegetations on the inflammatory sore rise above the level of the surrounding parts, bleed profusely when they are touched, or even separate partially. Inflammatory ulceration of the cervix is rarely if ever excavated; it is always on a level with or above the non-ulcerated tissues, and its margin never presents any abrupt induration. Hence the difficulty of determining its existence and limits by the touch, and the source of differences of opinion as to the existence of ulceration of this part. The cervix very seldom presents more than one ulceration situated around the mouth, dipping into its cavity, and extending more or less on the outer surface. If the ulcerated state consist of several patches, it may be referred to aphthous or ulcerated mucous follicles.

27. The form of the os uteri is generally changed, owing to the existence of the ulcerated state now described both within and around this part. The lips of the os swell, enlarge, expand, and open the cervical canal. This opening varies with the hastened or slowed state of the changes above described, but it is generally greatest in females who have had several children. When with these changes the lips of the os uteri are much hypertrophied and indurated, the opening may admit the first phalanx of one or even of two fingers; and it may then assume the form of two segments of a sphere, separated by a deep fissure, within which the ulcerated surface is situated.

28. Ulceration, or the changes now described as constituting the ulcerative state of the cervix and os uteri, gives to the surface of these parts a soft, velvety character, when examined by the touch. The state of the os uteri are the chief indications which this sense can furnish of the existence of this lesion; but, as ulceration alone will open the cervical canal, and as the velvety sensation cannot be depended upon, the existence of ulceration can only be determined by an instrumental examination. The state of the parts, detailed by touch and the symptoms about to be noticed, warrant a resource to this examination. In nearly all the cases in which ulceration occupies the exterior of the cervix, it will also be found, on examination, to penetrate more or less deeply into its cavity. The entire canal of the cervix, as far as the os uteri may be ulcerated. Even when the cervical canal is free from ulceration, if ulceration exists externally, it is generally inflamed to a greater or less depth."

The natural coaction of the os internum appears generally to constitute a barrier to the extension of ulceration into the cavity of the uterus. But to this rule there are exceptions, as regards the inflammatory state, which obviously extends in many instances.

29. d. The discharges from the vagina caused by chronic inflammation of the cervix uteri are identical with those which are described under the head of Lacerations. For, as I described them, in that article, as resulting from inflammatory action, as evinced by the local and general symptoms (see § 19. et seq.), their connection with the changes above described and disclosed by the speculum is obvious. The discharge generally consists of varying proportions of mucus and pus, in which it is rarely the luteal or second, unless the inflammation be specific or gonorrheal. It is not infrequently tinged with blood, especially after violent exertion or sexual intercourse. In these circumstances, the blood is exuded from the ulcerated or granular surface and is seldom in considerable quantity — when in quantity it may be unmix ed with the muco-puriform discharge.

30. e. Hyper trophy of the neck of the uterus is generally a consequence of chronic inflammatory action, congestion and swelling of this part being an early result. It may, however, remain long without further change; its structure retaining its softness and elasticity. After a time, the exudation of plastic lymph in the interstices of its structure either is considerable, or becomes partially organised, and renders it both hypertrophied and indurated. At first, the inflammatory action is often acute, as indicated by increased heat, vivid redness, and tenderness on pressure; but these signs subside, the hypertrophy advancing with more chronic indications; and sometimes so far as to very greatly increase the size of the cervix. In virgins and women who have not had children, the cervix seldom enlarges to any great extent. It may, on the other hand, be increased in size: but when it is enlarged in this class of patients it seldom is more than two or three times the natural size. In women who have borne children the hypertrophy of the cervix with induration may, according to Dr. J. Henry Benner, in extreme cases reach the size of the fist. Some French writers ascribe the ulcerations existing in these cases to the hypertrophy, but he justly contends that the ulceration may commence as early as the hypertrophy and advance with it; and he has seen ulceration confined to one lip, accompanied with induration and hypertrophy of that lip only. When the causes of these changes in the cervix has followed a miscarriage or delivery, the hypertrophy is generally the more remarkable. Hypertrophy and induration are commonly confined to the cervix, but sometimes they extend to the body of the uterus, indicating that it is also the seat of chronic inflammation.

31. As the indurated cervix enlarges, the external opening expands and assumes a transverse form; so that instead of a nearly circular orifice, there is a deep fissure with well-defined lips.
This occurs more especially when the induration is attended by ulceration. Sometimes one of these lips may be many times larger than the other. When the superior lip is much enlarged it covers the os uteri, which is underneath it: when the inferior one is thus changed the os is above it. Dr. H. Bennett says that he has seen both the superior and the inferior lips separately enlarged to such an extent as to form a kind of tumour projecting a couple of inches beyond the non-hypertrophied lip. He states that the hypertrophied cervix is sometimes divided into separate lobes, owing to asseverated laceration of the cervix during an abortion or instrumental labour. The laceration not healing, the ulceration in the course of time is followed by hypertrophy of the segments into which the cervix is divided. These segments sometimes assume a stony hardness; and they may be mistaken for seirrhæs; but may be distinguished from that malady as follows:—

"When the lobular, knotty irregular condition of the cervix is the result of laceration, and is simply inflammatory, the fissures which separate the lobes radiate round the cavity of the os as a centre,—which is not the case in a carcinous tumour—each of the lobes being perfectly smooth in itself, and free from tubercles, or superficial irregularities. Not only is this lobular form of induration erroneously considered cancerous, but even the hard inflammatory hypertrophy is still more erroneously considered to be frequently malignant."

32. **Displacement** is often consequent upon inflammatory hypertrophy of the cervix; the entire organ generally descends, and the cervix is thus brought nearer the vulva, and at the same time directed backwards. The retroversion of the neck of the uterus is commonly met with in married females suffering from inflammatory induration. With them it is chiefly owing to intercourse; and generally becomes permanent. Enlargement and induration, when very considerable, often occasion more or less prolapse, unless the vagina be very contractile. In women who have had many children, and whom the vagina is lax, and offers an insufficient support to the uterus, the prolapse may be so great, especially when standing, as to reach the vulva, or even to appear externally. When the cervix thus lies low in the vagina, a sensation of weight, dragging, and bearing down is experienced, especially when erect. This sensation is caused by the traction of the organ on its ligaments and organs with which it is connected, and by the pressure of the cervix on the vagina and vulva. The hypertrophied cervix may be directed anteriorly, or behind the pubis, and be more or less high. This position is generally owing to some enlargement of the body of the uterus, causing the organ to fall back into the cavity of the sacrum, thus throwing up the cervix. The enlarged cervix occasionally lies diagonally, or to either side, but this position seldom amounts to a diseased condition.

**Pain** is not always experienced in chronic inflammation of the neck of the uterus, and when it is felt, the situation of it is very often such as not to designate the seat of disease. In some cases pain is almost or entirely absent, although there may be leukorrhæa discharge, and considerable constriictional disturbance, even with slight febrile symptoms towards evening. My experience enables me to vouch for the accuracy of Dr. J. H. Bennett's remarks respecting the seat of pain; for in several cases to which I have been called, an examination has confirmed the connection of the pain with the local affection. The pain is dull, aching, numbness, and generally circumscribed, usually felt in one or both the ovarian regions, but much more frequently in the left than in the right; pain of a similar character is also often experienced in the back; and even still more frequently, according to my experience, in the lower region of the sacrum, just above the os coccygis. When it is felt in this situation the neck of the uterus will be found low in, and pressing upon the posterior walls of, the vagina. Sometimes the pain in the back is scarcely perceptible, or is described only as a "weakness," excepting after fatigue, when it is usually more severe. The patient says that her back is broken, and that she can neither stand, sit, nor walk with comfort. "When there is pain in the region of the uterine neck, it is experienced behind and above the pubis. It is seldom circumscribed, like the ovarian pain, but radiates all over the perineal region and along the three pairs—the lumbo-sacral, the ovarian, and the lower hypo-gastric (I name them in the order of their relative frequency), may exist conjointly or separately. They are produced alike by inflammation without ulceration, and by inflammation with ulceration. They are, however, much more marked when there is ulceration, more frequently severe, and much more constant."

34. These pains are not to be mistaken for **neuralgia** of the uterus, which is much more acute, comes on suddenly after intervals, and ceases as suddenly, and is seated in the uterus itself, (§§ 14, et seq.) The neuralgic pain is sometimes present only for an hour or two, and rarely longer than ten or twelve hours, the intervals being characterised by freedom from pain. It is sometimes symptomatic of organic disease of the womb, as fibrous tumours in the structure of the organ. But it is often felt independently of any evident lesion, the os and cervix uteri being healthy and free from any morbid sensibility.

35. In addition to the pains described, the patient sometimes complains of pain in the hip, round the crista of the ilium, in the groin, and down the thigh; posteriorly along the course of the sciatic nerve and its divisions; and anteriorly and internally along the course of the anterior crural and obturator nerves. These pains have referred rather to chronic inflammation of the inner surface of the uterus and enlargement of the organ than to chronic inflammation of the cervix. In the latter case they may be caused by deficient support of the vagina, partial prolapse and pressure; in the latter case, they may be sympathetic. The pains caused by diseases of the uterus are always increased by standing, sitting, walking, and exertion, but relieved by reclining and the horizontal posture.

36. **The functions of the uterus** are often interfered with during the continuance of chronic inflammation of the cervix. As respects menstruation, it may be stated, that it may, for a time, go on without any marked change. But it usually becomes more painful, very scanty, or excessively abundant, and irregular as to the interval, the
UTERUS — INFLAMMATION OF THE NECK OF.

duration, and the quantity. The pains, especially on its accession of this period, are greatly increased in the situations above described, and are often attended by retchings and vomiting, by recurring uterine pains, the becoming incisional, the loss of appetite, nausea, and vomiting generally present to have been too often imputed to this disorder of the digestive organs, instead of these complaints being regarded as results of the inflammation of the cervix. The urinary function is often more or less disturbed, in respect both of the micturition and of the menstruation, and of the frequency of the calls to discharge this secretion and the sensations attending the act. Dyuria is sometimes complained of, and a portion of the secretion from the inflamed cervix often passes from the vagina at the time of micturition.

37. This disease must necessarily be a cause of sterility, in many instances; the morbid states of the cervix and os, and the discharges from them, interfering more or less with impregnation, not only in recently married females, but also in women who have borne children. Some females, however, become pregnant notwithstanding the existence of extensive disease of these parts; but when it takes place under these circumstances, it is generally painful, and apt to terminate in abortion. Sterility proceeding from this disease may be removed by curing its cause. Dr. Bennet states that he is continually seeing patients, who have ceased child-bearing for years, owing to inflammatory disease of the cervix, recover the power of procreation when cured. Sometimes they become pregnant even before they are quite well, in which case they seldom miscarry, even if the treatment is suspended, although the pregnancy is often laborious.

38. 1. Utterine inactivity, or exhaustion, is often a symptom of chronic inflammation of the os and cervix uteri, especially when attended by profuse leucorrhoea and ulceration or granulations, or when the disease is severe. Dr. J. H. Benet remarks that this absence of natural sensations, or sexual desire, sometimes exists independently of any physical pain, and occasions great unhappiness in married life. He attributes this change to the modified vitality of the diseased uterine organs, and impaired general health. The cases of this description, which I have met with, have been chiefly those in which there was reason to believe that the complaint had been caused by self-pollutions, and where the tenderness of the os uteri and adjoining parts rendered sexual congress more or less painful; for instances are not rare of masturbation being persisted in, although marital congress is resisted or evaded. When the cervix is so tender from this disease as to render congress painful, the sensation is experienced at the time, and for some hours afterwards, or even longer. It may be felt either behind the pubis, or in its usual situations. But, although the disease may be severe, the cervix being ulcerated and enlarged, congress may not be painful. Whether painful or not painful — the former especially — this act may be followed by a discharge of a little blood, or even by considerable hemorrhage. That the evasion of marital congress is owing rather to the circumstance just adverted to, than to the disease of the cervix, is evinced by the fact that such evasion is not manifested in other diseases of the uterus, or very rarely.

39. Constitutional and general symptoms are always present when the cervix uteri is diseased. It should not be overlooked that this part of the uterus possesses marked sensibility and intimate relations with all parts of the economy, through the medium chiefly of the ganglial and sympathetic system. Hence the digestive functions are more or less disordered according to the duration and severity of the local complaint; and there are frequently both nausea and vomiting on the accession of the catamenium. The disorder of the stomach and digestive organs is often somewhat similar to that consequent on early pregnancy, and uterine tumors, the last two being avowed or neglected, the mesocolic, or mesenteric, or hydropic variant of the typhoid fever and the true typhoid fever, or the typhoenteric variant of the typhoid fever and the true typhoid fever. The typhoid fever and the true typhoid fever are the typhoid fever and the true typhoid fever.

40. The pulse is sometimes very materially affected, and becomes more or less accelerated towards evening; and as debility increases, it is generally weak, or small and irregular, and readily accelerated on any mental or physical excitement. A protracted state of the disease, especially when inflammation is curbed, is characterized by increased perspiration, and abundant leucorrheal discharge, ultimately occasions anemia, pallor, a sickly or sallow appearance of the countenance, loss of flesh, and a flabby state of the muscular structure. Contingent upon the course of the disease, various sympathetic affections often appear, especially nervous headache, depression of mind, a sense of weight or pressure at the summit of the head or on the forehead, pain and tenderness in the course of the spine, and numerous hysterical symptoms. These phenomena are generally exacerbated during the catamemorial period, especially when this period is disturbed in any way. Most of the symptoms described in the articles Hysteria and Sexual Irritation originate in this disease of the cervix and os uteri.

41. Dr. J. H. Benet was the first who gave full accounts of the diseases of the cervix of the uterus; and he was followed by Dr. Whiitedead of Manchester, Professor Simpson of Edinburgh, and Professor Miller of Louisville, U. S. Various other writers on uterine disease have coquetted with the subject, and, after having endeavoured to controvert the statements of these physicians, have at last fallen in with their views. From these and other sources of information, furnished not only in this country, but even much more abundantly on the continent, as will be seen in the Bibliography, the great importance of inflammatory disease of the cervix uteri is made apparent. Dr. Whiitedead has given an enumeration of the lesions of this part of the uterus; and, although I do not profess this or any other specialty, but endeavour to practise as a physician in all medical cases, yet I am sometimes consulted respecting uterine diseases; and I am thus enabled from some experience to say that the statements and descriptions furnished by the physicians whom I have mentioned, are unanswerable.

42. "1st. Inflammation and superficial erosion, implicating one or both lips of the os uteri, and more or less of the external and internal cervix; — 2d. Varicocele ulceration, commonly occupying the back part of the anterior lip, sometimes continued to the posterior lip, and occasionally implicating both. It gives rise to hemorrhages obeying, more or less perfectly, the vesical periods,"
and to purulent discharges in the intervals,—3d, Edema of the cervix; — 4th, Fissured ulceration of one or both commissures, of the anterior or posterior lip, or implicating all these parts at the same time, with or without abrasion of surface; — 6th, Endometritis, or inflammation of the lining membrane of the uterus, affecting the body as well as the neck, and sometimes accompanied with induration of the cervix, or erosion of one or both lips of the os uteri; — 7th, Folicular ulceration; — 8th, Gonococcal inflammation, affecting the lips and adjacent cervix, and especially liable to spread to the lining membrane of the entire organ; — 9th, Syphilitic disease, in its primary, secondary, and tertiary stages; — 10th, Prolapsum uteri, which owes most commonly its existence to disease of the lower part of the uterus, as the primary exciting condition."

45. To this enumeration of lesions, given by Dr. Whitehead, may be added hypertrophy, with or without ulceration, or granulation, or dilatation of the cervical canal. This, in one or other of these states, is a frequent consequence of chronic inflammation of the cervix. Generealized inflammation of the cervix and its canal is of greater importance than is usually considered. I have seen several instances of this form of disease; and in nearly all it extended to the lining membrane of the uterus, and was accompanied with great suffering. In nine cases of married ladies, not only did this extension occur, but the cervix also became remarkably enlarged. Recovery ultimately took place; but the ovaria remained more or less enlarged in all.

44. C. In the virgin and unmarried female, inflammation and its consequences noticed above are by no means inefrequent; and, although partially described by me in the article Leucorrhoea in the section on "Leucorrhoea from inflammatory irritation of the mucous glands of the os and cervix uteri" (§ 19. et seq.) before the appearance of Dr. Henry Bennett's work, yet to him the distinction is justly due of having widely and elucidated this subject in respect of this class of patients; and I can fully corroborate his statement that inflammation and ulceration of the cervix uteri in the virgin is not an uncommon disease, and that it may be referred most of the severe forms of dysmenorrhea and leucorrhoea which resist the ordinary modes of treatment. Even within these few months I have been called to several cases, under the care of other practitioners, where this disease existed, from ages varying from nineteen to thirty. Scanty, excessive, and irregular menstruation, as well as the complaints just mentioned, not infrequently proceed from inflammatory states of the cervix, and internal surface of the uterus, as shown in the article on Menstruation. (See more especially §§ 65—129.)

45. The causes of inflammation of the cervix uteri in unmarried females have been already noticed. (Y2) The symptoms in them are not materially different from those already described: the permanency of a leucorrhoeal discharge; the local pains; dysmenorrhoea, and otherwise disordered menstruation; spinal irritation; sympathetic pains in the hips, thighs, spine, and under the left mamma; bearing down, weight in the pelvis, debility, and anemia, emaciation, &c. In addition to these, partial prolapse of the uterus, and other deviations of its position, are not infrequent in this class of patients.

46. D. During pregnancy inflammation and ulceration of the os and cervix uteri may be present, having existed previously, or supervened subsequently to impregnation. MM. Bove de Lévy and Costilhes first noticed this state of the disease; and soon afterwards Dr. Henry Bennett, in 1846, and Dr. Whitehead, in 1847, fully illustrated this association of inflammation of the cervix uteri. Dr. Bennett remarks that he formerly believed that the disease mostly originated subsequently to conception. This opinion, however, his later experience on a wider field has shown to be erroneous. Although it sometimes thus originates, the cervix is diseased in the majority of cases previous to conception. He adds that the disease generally produces sterility when it attacks young married females at the onset of their married life, but not so generally arrests conception when they have had children before they are attacked. The indications furnished by tactile and ocular examinations in this state of the disease are as already described. The disease is attended by pain in the back, sacrum, above and behind the pubes; and by a sense of weight and bearing down, and mucous-purulent discharge. As pregnancy advances the pains increase; the sickliness and vomitings attending this state become severe; and the mucous-purulent discharge is often accompanied with more or less hemorrhage. Dr. H. Bennett has very satisfactorily shown that this disease in the pregnant state is often a cause of the various disorders complained of in this state, or hemorrhage, obstate sickness, death of the fetus, abortion, moles, &c.; and Dr. Whitehead has fully corroborated this statement. These are most important practical facts; and, however sneered at by some, doubted by others, and disbelieved by a few, I have had ocasions, since the date above mentioned, to be convinced of the truth of the statements made by these physicians. I may here adduce a summation of Dr. Whitehead's researches on the influence of the lesions under consideration in producing abortions; and in this he confirms what had been previously adduced by Dr. H. Bennett. Infectious ulceration was the cause of abortion in 26 in every 100 cases; and this event occurred between the middle of the sixth and the middle of the ninth month of pregnancy. Vaginose ulceration induced abortion in 6 or 8 out of every 100; and it operated during the latter two or three months. Edema of the cervix, acting likewise in advanced pregnancy, was observed in about 1 in 25 or 30 cases. Fissured ulceration was found to exist in 20 to 24 out of every 100 cases, and may cause abortion from the fourth to the middle of the seventh month.

47. E. During and after abortion inflammation, ulceration and induration of the neck of the uterus are often productive of much pain. The symptoms in them are not materially different from those already described: the permanency of a leucorrhoeal discharge; the local pains; dysmenorrhea, and otherwise disordered menstruation; spinal irritation; sympathetic pains in the hips, thighs, spine, and under the left mamma; bearing down, weight in the pelvis, debility, and anemia, emaciation, &c. In addition to these, partial prolapse of the uterus, and
UTERUS.—Inflammation of its Body.—Acute Metritis.

In this part, this cavity may be somewhat enlarged, as, indeed, the whole organ frequently is in these circumstances. If, in addition to the discharge just noticed, there be a dull, deep-seated pain behind and slightly above the pubis, and more or less general febrile reaction, endo-metritis may be confidently inferred. Since, in the introduction of the uterine fundus, and its improvement by Professor Simpson, a recourse to it has been considered as a means of diagnosis in endo-metritis; for, if the os internum of the cervix be so completely open as to allow the uterine sound to pass freely into the uterine cavity, and if this cavity be increased in size, and be more sensitive, the above symptoms being also present, this complaint is certainly present. But endo-metritis may exist and not be attended by the sero-sanguinolent discharge alluded to. It is only when the inflammation is most severe that it is present. In the less severe and congestive states, it is characterised by the discharge and the symptoms described in the sections on Leucorrhoea above referred to, and, during the menstrual periods, by the painful, difficult, inflammatory, or hemorrhagic symptoms described in the article Menstruation. (See §§ 70–129.)

51. As endo-metritis is commonly attended by chronic inflammation of the cervix and os uteri, the symptoms of the latter are generally present. Nevertheless, the former gives rise to nearly the same symptoms; yet the deep-seated and constant pain behind and partly above the pubis, the sensation of weight and bearing down, the swollen, sensitive, and enlarged conditions of the organ evinced on examination, the states of the discharge and of menstruation already noticed, and the accompanying febrile action, although often slight, but always increased towards night, sufficiently indicate the nature of the disease.

52. The progress and terminations of endo-metritis depend much upon its causes and the circumstances in which it originated. It is often attended by more or less inflammatory action in the cervical canal, and in the substance of the organ; and, according to the extent of this association, to the occurrence of the disease after difficult or instrumental labours or after abortions, and to the domestic, moral, and hygienic conditions of the patient, the course, duration, and termination of the complaint should be imputed. A chronic form of the disease is apt to supervene, especially in the circumstances now alluded to; and even in favourable cases the acute form generally passes into the chronic, the constant discharges from the internal surface and neck of the uterus, whether sanguinolent, serous, mucous or purulent, and the catamenial discharges, whether difficult, scanty, or excessive, or attended by coagula, or by plastic exudations, ultimately tend to reduce the acute into a chronic form of the disease. Ulceration of the internal surface of the uterus has been rarely noticed as a consequence of endo-metritis. When this occurs, the cavity of the uterus is considerably enlarged, and contains pus, mucus, and a bloody matter, which are discharges more or less freely, and often at intervals.

53. B. Acute Metritis, in the non-puerperal state, is a rare disease. At the commencement...
UTERUS.—INFLAMMATION OF
its BODY.—ACUTE METRITIS.

From certain septic emanations, especially in females who have had children. I was called to two families living in the opposite outskirts of London, during a very warm autumn, after a hot summer. The privies of both houses were open, very full, and offensive. Several younger members of these families were attacked by dysentery, with distressing tenesmus, and their mothers became the subjects of both the dysenteric affection and asthenic inflammation of the vulva, rapidly extending to the vagina, and to the neck and body of the uterus. In both these cases the symptoms of acute metritis were unmistakable and most violent, and were, with the dysenteric affection, manifestly caused by the state of the privies, to which, indeed, the patients themselves referred them. I have, both in this and in foreign countries, had frequent reason to impute the occurrence of Dysentery (see § 24.) to open privies, &c.; but these two are the only instances I recollect of both dysentery and acute metritis having appeared contemporaneously in the same female.

b. Symptoms.—The patient complains of severe and constant pain deeply seated in the hypogastric region, chiefly behind and above the pubis, darting into the ovarian regions, around the hips, and sometimes down the thighs, with a sensation of weight and uneasiness in the pelvis, and of severe pain of the lower lumbar, lumbo-dorsal, and sacral regions. Pain on firm pressure is felt just above the pubis, in the median line, and equally to the right and left of that line. On examination, the vagina is generally hot and dry; the cervix and os uteri are swollen and sensitive to the touch or to pressure. The body of the uterus is enlarged, and attempts to ascertain its size are attended by extreme pain, and often by nausea or retching. The symptoms are always aggravated by sitting down on a hard seat, or by an examination per vaginam, and the patient is unable to walk or stand, or to sit up in bed. She generally lies on her back with her knees drawn partially upwards. Calls to pass urine are frequent, and attended by dysuria. The bowels are usually constipated, and eructative motions are passed with extreme difficulty, and small shocks, the throbbing of the faces being surrounded by much mucus. In many cases violent paroxysms of pain occur after intervals of comparative ease.

56. (This acute state of the disease is not often preceded by chills or rigors, and it is at first not attended by any vaginal discharge, unless it have supervened upon vaginitis, or endo-metritis, as in some cases of asthenie or diffusive inflammation of the vagina and vulva. However, when the inflammation has commenced in, or extended to, the inner surface of the uterus (§ 50.), a sero-sanguineous, or purulent discharge takes its place. As thickened at first with dysenteric tenesmus, manifestly owing to inflammatory action which had commenced in the rectum and sigmoid flexure of the colon. Soon afterwards unmistakable evidence of acute metritis appeared. This lady had not conceived for several years. Soon after the full development of the metritis, a woman, who was attacked by dysenteric, pale yellow, albuminous vomitus and watery, dysenteric stools, followed by copious diuresis, of various appearances, occurs. In addition to the usual febrile or constitutional symptoms, especially thirst, restlessness, scanty, high-coloured urine, constipation, headache, want of sleep, &c., there are constant nausea; a white or ferruginous tongue; pain and swelling of the mammary, and some suffering, pellagra, hemiplegia alba dorsis of the left thigh began to appear, and when the subsidence of it commenced, the right thigh became similarly affected. She ultimately recovered. But disease may commence almost simultaneously in the rectum and vulva. From certain septic emanations, especially in females who have had children. I was called to two families living in the opposite outskirts of London, during a very warm autumn, after a hot summer. The privies of both houses were open, very full, and offensive. Several younger members of these families were attacked by dysentery, with distressing tenesmus, and their mothers became the subjects of both the dysenteric affection and asthenic inflammation of the vulva, rapidly extending to the vagina, and to the neck and body of the uterus. In both these cases the symptoms of acute metritis were unmistakable and most violent, and were, with the dysenteric affection, manifestly caused by the state of the privies, to which, indeed, the patients themselves referred them. I have, both in this and in foreign countries, had frequent reason to impute the occurrence of Dysentery (see § 24.) to open privies, &c.; but these two are the only instances I recollect of both dysentery and acute metritis having appeared contemporaneously in the same female.

57. c. Terminations.—In from seven to four—

55.
UTERUS.—INFLAMMATION OF ITS BODY.—CHRONIC METRITIS.

After ten days the disease subsides, generally without either suppuration or inflammation of the uterine veins, in the non-puerperal state; but this latter result may occur in this state, as shown in the case attended by Dr. R. Lee and myself (§ 54.), and in two other cases for which I was consulted, and which terminated fatally, the uterine phlebitis was paroxysmal by secondary purulent formations, as shown by examination after death. It is chiefly in the cachectic habit of body in females addicted to intoxicating liquors, as in one of the two cases just now alluded to; and when the causes are of a septic or infecting nature, and the disease assumes an atypical character, that either the veins become implicated on the one hand, or the peritoneum on the other.

56. Acute metritis may degenerate into the chronic state, and occasion the inflammatory forms of Leucorrhoea and of disordered Menstruation, (see those Articles), or various consecutive lesions; and it may give rise to purulent collections, either near to, or even in the cavity of the uterus. In either case the collection, as it becomes increased, is evacuated sometimes more or less suddenly, and after a greater or less increase of suffering per vaginam. When matter is formed near the outer surface, it most frequently extends to the cellular tissue between the lateral ligaments, and finds its way, as in cases of suppurition occurring in those ligaments.

59. a. The Prognosis of acute non-puerperal metritis is generally favourable when the constitution of the patient is sound; when the disease is treated promptly and judiciously, and the causes are not of a contaminating or specific nature, as in the cases above alluded to (§ 54.). In drunken females, in the cachetic, and when the disease has been produced by infectious or contaminating agents, the extension of inflammation to the ovaries, to the veins, or to the peritoneum, should be dreaded; and in either case the patient's life may be placed in the utmost jeopardy. Even if the acute should lapse into the chronic state, or give rise to chronic inflammation of the lateral ligaments, much and prolonged suffering will result.

56. a. Diagnosis.—Acute metritis may be mistaken for acute cystitis, or the latter for the former. But a careful examination of the hypogastric region, of the state of parts per vaginam, and of the condition of the urine and the phenomena attending the discharge of it, will readily disclose the organ affected. When the lateral ligaments are inflamed, the pain and tenderness on pressure are experienced on one side of the median line, or in one side of the pelvis; “and the finger passed up towards the uterus, detects the inflammatory tumour lying on one side of the uterus.”

61. f. Examinations after death from acute metritis in a non-puerperal state are rare, unless death has been caused by uterine phlebitis or by peritonitis, as in the cases alluded to above which occurred in my practice. In these cases, the uterus was considerably enlarged, and very much softened, especially towards its internal surface. The substance of the organ was infiltrated with a thick, non-purulent fluid, and with a greenish brown fluid in the other. The cavity of the uterus was much enlarged in both, but much more so in one than in the other, and its surface was covered with a chocolate-coloured or rusty exudation in the one, and by a rusty purulent exudation in the other; this latter containing a little of a softer matter of the same appearance and of an offensive odour. The spermatic veins were inflamed, and contained coagulated blood, phlebitis extending throughout the uterine and spermatic veins to the vena cava, with coagula mixed with an ichyous thick pus matter.

In one case purulent collections, more or less of a semi-fluid appearance, and offensive odour, existed in the liver; and in another, matter was formed in one of the eyes, which had burst shortly before death. In a third case above alluded to (§ 57.) peritonitis supervened, the uterus presenting but slight alterations of structure; but the peritonitis exhibited the lesions described in the article on this membrane. (See §§ 80. et seq.)

62. C. SUB-ACUTE AND CHRONIC METRITIS.

Sub-acute metritis is merely a less severe form of the acute, most of the symptoms described above (§§ 53. et seq.) being present, but in a slighter degree. The chronic form of the disease may, like the acute, vary much in severity; but, unlike it as respects frequency, is a common form in its simple and complicated states. It generally is seated in a part of the body of the uterus; and, in the opinion of Dr. H. Benner, in nine cases out of ten in the posterior wall of the organ, in its inferior region, adjoining the base of the cervix. It is commonly the result of extension of chronic inflammation of the cervix, and in some instances of the acute or sub-acute state of the disease. In these instances it may exist either in the anterior or posterior wall, or in one of the lateral walls, of the uterus.

63. a. The symptoms vary much with the exact seat of the disease, and with the periods during or near menstruation. In the intervals between these periods, the patients are comparatively easy; the local symptoms are either much mitigated, or but little complained of; and fever is either slight, or experienced chiefly in the evening or night. In many cases, however, the functions of digestion, assimilation, and nutrition are impaired, and various nervous symptoms are experienced. When the vascular determination preceding menstruation supervenes, then all the symptoms characterizing the disease are developed. A constant, dull, ach- ing pain is felt in the lower hypogastric region, behind and a little above the pubis, and in the left or right ovarian regions, most frequently the left. A dull aching pain is also present under the left mamma or in the left hypochondrium, in the lumbar-sacral region, extending around the hips, and down the sides of the thighs; and is often more complained of than the deep-seated pain in the pelvis. Walking, ascending a stair, or riding in a carriage, and every kind of motion, are extremely painful, more especially before, during, and after menstruation, and in some cases, they are then agonising. On the accession of this period, the patient's sufferings are sometimes aggravated by coldness and vomiting.

64. On examination per vaginam, in addition to co-existing disease of the cervix, the seat of disease is easily detected. The finger, when passed to the base of the cervix, and then meets with an exceedingly sensitive elevation, in some cases regular, in others irregular, but spherical. Pressure on the tumefied part is very painful. Occasionally there is hardly any ex-
1232 UTERUS—INFLAMMATION OF ITS BODY.—CHRONIC METRITIS.

capable swelling, but exquisite tenderness; pressure giving rise to sickness. The womb is generally movable, but the attempt to move it is attended by pain and nausea. Owing to its mobility, inflammation and enlargement of a portion of the uterus is generally attended by more disorder of the peritoneal organs, less in the direction of its enlargement. If the posterior wall is the seat of enlargement, as is most commonly the case, the organ falls backwards toward the cavity of the sacrum, and the cervix is turned upwards and towards the pubis; producing retroversion; but never in such a manner as to press upon the urethra, as sometimes occurs in retroversion during pregnancy. The cervix, however, may remain in its usual position, and not be anteverted, it forming an angle with the body of the uterus, which is said to be retroflexed. If it be the anterior wall which is tunnelled, the uterus may fall forwards, especially in married females, and occasion anteversion. When retroversion is connected with much enlargement, the uterus presses upon the rectum, and becomes a mechanical obstruction to the process of defaecation. In both forms also of displacement, especially with chronic metritis, the mechanical functions of the urinary bladder result, the cat's to urinate being often, difficult, or otherwise affected. Chronic metritis affecting chiefly one of the sides of the uterus, or associated with disease of the appendages of that side, may likewise occasion more or less displacement in that direction; but this is comparatively rare. Chronic metritis may not be necessarily attended by any vaginal discharge; but such discharge is most frequent, owing to the co-existence of inflammation of the cervix and vagina, and is either mucous-purulent, or purulent with a more or less sanguineous tinge.

65. a. The constitutional symptoms of this disease, especially when protracted, are well-marked, and are, according to my observation, well described by Professor Simpson and Dr. H. Bennett. The countenance is generally pale and sallow, and offers an expression of languor and pain; the "facies uterina," being more especially palpable in inflammation, and particularly during or near the period of menstruation. Emaciation is a frequent sign, although not always recognised or recognisable at first. Nausea is generally present; in the most severe cases, it is almost constant; in the less severe, only at the accession or during menstruation. Nausea, or sickness with loathing of food, but without vomiting, is so characteristic a symptom of metritis that, when it is present in chronic inflammation of the cervix, the extension of the disease to the body of the uterus may be inferred. Besides the intimate sympathy existing between the stomach and uterus, numerous other sympathetic derangements occur in the course of the disease, more especially palpitations, heartburn, headache, feverishness, want of sleep, restlessness, morbid states of the urine, constipation, dysuria, painful defaecation, &c.

The progredient and terminations of chronic metritis are very variable. It is generally present for some time before the symptoms mentioned above are developed. It is at first attended by slight or obscure symptoms, which become more severe about the period of menstruation, and more and more constant with the advance of time, until the patient is prostrated by their severity and continuance. Whilst recurring metritis, by the vascular determination and congestion characterising it, tends to exacerbate the disease, the vascular discharge, especially when considerable, reduces the severity of it, favouring a partial resolution, and perpetuating the chronic condition, when unaided by judicious treatment. When, with the periodical exacerbations, other causes of developing uterine inflammation are conjoined, the chronic may pass on to the acute form, and, in either form, may be extended to the uterine appendages, or even to the peritoneal surface. Cancerous degeneration of this state can rarely or never occur, unless in the cancerous diathesis. The most common consequences of chronic metritis are those already noticed, namely, displacements, enlargements, and the extension of the disease to adjoining organs or parts.

67. d. Diagnosis.—Patients affected with chronic metritis, existing either simply or with chronic inflammation and ulceration of the cervix, but a few years ago, were generally considered as subject only to functional dysmenorrhoea, or to displacements of the uterus. Dr. Henry Bennett referred these last disorder of the cervix, and saw them when present as consequences of metritis, which, however, might exist without having as yet been followed by these consequences. Whether or no displacements of the womb ever occur without previous inflammation and its consequences, enlargement, &c., becomes a question, and one which requires solution; but there appears no reason to doubt the fact of the latter often producing, and frequently being associated with, the former. However, it should not be overlooked, that, when an enlargement of the uterus is great, when it is not attended by any considerable pain or tenderness on pressure, it very probably arises from the formation of a fibrous tumour in the uterine walls. In these cases, there is generally displacement in the direction of the uterine tumour. When the tumour is large, it is often attended by more or less inflammatory action; and when this obtains, then both pain and tenderness may be exceedingly great, and particular also of the broad ligaments may be mistaken for chronic metritis, occupying the lateral region of the womb, especially if the tumour be lying on the uterus, as is often the case." The symptoms characterising the latter affection will be noticed in the sequel; but both affections are sometimes associated.

68. It may be difficult to distinguish cancer of the womb from chronic metritis. If the uterine swelling presents nodosities or irregularities of surface; if the pains are lancinating; if the general health is very much impaired; if the patient is sallow, cachectic, emaciated, anæmized, and weak, well-founded suspicions of cancer may be entertained. It is chiefly from the history of the case, and from the consideration of a variety of circumstances, that a correct diagnosis can be formed. Cancer most frequently commences in the cervix, and extends to the body of the organ. But in both situations it is either latent, or it does not come before the physician until it has made considerable progress. It is then, or it soon becomes, immovable, owing to adhesions between the uterus and surrounding tissues. "In chronic metritis there may be adhesions, but they are not
of the perfectly invulnerable nature of those observed in the malignant affection. In cancer, the nodosities and inequalities are sharp, knife-backed, irregular; in chronic metritis, they are spherical and regular in their irregularity. Cancerous tissues are seldom very sensitive to the touch, whereas it is the reverse with the inflamed uterus. Cancer has a tendency to progress and to pass through its periods in the course of a limited space of time, say one, two, or three years. The symptoms indicating the existence of chronic metritis, on the contrary, may generally be traced back for several years, and when recognised, the disease appears to remain nearly stationary, if left to itself. The consideration of these differences will also prevent cancer being mistaken for chronic metritis. If cancer of the uterus has become ulcerated, the distinction is still plain." (Op. cit. p. 44.)

69. D. Enlargement of the Body of the Uterus.—Hypertrophy of overgrowth of the uterus, more especially of its body, may in many cases be traced back for weeks or months to an abortion, or a severe labour, or to disease after delivery. It may, however, originate independently of any of the foregoing causes. As a consequence it commences without marked severity, generally with slight ailment only, and even when supervening upon abortion or delivery it manifests merely a state of incomplete convalescence. When inflammation in any form follows either abortion or delivery, the process by which the womb is restored in a few weeks to its condition previously to conception—the process of Involution, as termed by Rokitansky and West—is checked. This process takes place in the structure of the uterus, which, having performed its grand function, undergoes a state of degeneration, and a partial conversion into a fatty matter, rendering it more susceptible of being either absorbed or eliminated in the lochia. During the second week after parturition this process is most active; but it proceeds also during the third and even fourth week. The process of reconstruction soon follows, and, according to the German microscopists, cells, nuclei, caudate cells, and the various elements are supplied, with the organ is built up anew. The manner of this reconstruction has not been satisfactorily explained by histologists; but it appears most probable that this renewal goes on pari passu with the removal of the old materials. The interior of the uterus undergoes similar changes to those which take place in its substance. "It is not until its lining membrane, with the exception of that of the cervix, has been several times reproduced and then cast off in a state of fatty degeneration, that it resumes the same condition as before impregnation. The occurrence of inflammation appears to interrupt these processes, for, though fatty degeneration of the tissues takes place, yet the removal of the useless material is but imperfectly accomplished; while the elements of the new uterus are themselves, as soon as produced, subjected to the same alteration; and the organ remains long after all mischief has passed away, increased in size, and at the same time composed of a tissue inapt for all the physiological processes of conception, pregnancy and child-bearmg." (West, Lect. p. 92.) This result will follow not only the mild, or chronic, or sub-acute, states of inflammatory action developed in the organ during the process of involution, but even any excitement of the sexual organs occasioning determination of blood to the organ, more especially sexual intercourse too soon after delivery or abortion.

70. Symptoms, &c.—Enlargement of the uterus consequent upon deficient involution may continue a considerable time without causing more at first than protracted convalescence, and a feeling of local and general ailment; but generally further disorder ensues, often with increased organic lesion. A sense of weight and bearing down; pains deep in the pelvis, back, and sacrum, often extending to the hips and thighs, numbness or pains in the limbs; difficult and painful defecation, frequent micturition, &c., are usually complained of. After a time various complications of this lesion occur, more especially prolapse, retroversion, congestion or chronic inflammation, frequent, or difficult or excessive menstruation, &c.

71. True Hypertrophy, or enlargement of the uterus independently of defective involution, occurs in both married and unmarried females. Dr. West considers that it is met with in the former chiefly, and in the latter not at all. But in any case the frequent sexual intercourse does not produce it, though that leads to its own train of evils; but there has in many instances seemed good reason for associating the condition with the imperfect performance of that function, and sometimes the evidences of that being the case have been conclusive." There can be no doubt of this being a not infrequent cause; although it is not the only organic lesion consequent upon this cause, ovarian disease being perhaps an equally frequent result. Although true or primary hypertrophy of the uterus may be most frequent in married females, it is by no means rare in the unmarried, especially after twenty-six or twenty-eight years of age, where there is reason to infer that the vice of masturbation has been long practised. It is, in this class, as well as in widows, and in married women who have either impotent, or nearly impotent, husbands, a consequence of the gratification of sexual desire. Sexual intercourse is imperfectly performed, and although frequently attempted, never duly consummated; and thus congestion of, or active vascular determination to, the uterus is maintained, without conception and its successive changes taking place, whereby the mischief resulting from reiterated and inefficient sexual efforts are prevented. —Hypertrophy of the week of the uterus has already been noticed (§§ 50, 51). Enlargements which result from the development of tumours in the organ are more appropriately considered in the sequel.

72. iii. Inflammation and Abscess of the Fallopian Tubes and Cellular Tissue.—Inflammation and abscess of the uterine appendages were, until recently, described only as a disease of the puerperal state. Under the head Ovaria, I have considered inflammation and other diseases of these organs, independently of the puerperal state; and in the article on Puerperal Diseases, "Puerperal Inflammations of the Uterine Appendages," have received due attention (§§ 187. et seq.). It now only remains for me to describe inflammation and abscess of the Fallopian Tubes and Cellular Tissues, independently of the
puerperal conditions. This disease has been noticed by MM. Gendrin, Velpeau, Marshall de Calvi, and by Dr. Dornney, Churchile, and Leaver; but it was not fully discussed until Dr. Henry Bennet directed the attention of the public to it in his Report on Inflammation of the Uterus and Appendages. This malady in the puerperal states is always severe and generally dangerous; but, in the non-puerperal conditions, it is commonly much more mild, and is often either not recognised or confounded with other diseases. Indeed, inflammation of the uterine appendages occurring after parturition presents as great difference from the same disease in the ordinary state of the system as puerperal metritis offers to non-puerperal metritis. In the puerperal states of these maladies, as I have shown, inflammations of the womb, ovaries, Fallopian tubes, cellular tissues, &c., have a tendency to extend to the peritoneum, or to diffuse themselves, and produce most important and often fatal consecutive changes. But in the non-puerperal form, there is a tendency to assume the sphenoid, instead of the ashenic diathesis, and to limit itself to the tissues primarily attacked; generally spreading to the side of other consecutive or fatal alterations rarely occurring.

73. a. The causes of non-puerperal inflammation of the Fallopian tubes are the same as those which more commonly produce metritis (§ 10. 22.) and ovaritis (§ 6. et seq.); especially arrested menstruation, disordered states of this function, and abortive impregnation.

74. The inflammation may originate either in the cellular tissue, in the ovaries, in the tubes, or in the uterus, the disease of the one structure being more or less to the others. This extension of inflammatory action from the one part to the other and to the peritoneum is most remarkable in the puerperal states (see Ovaria, §§ 6. et seq., Art. Puerperal Disease, §§ 181. et seq.), but it is much less so in the non-puerperal condition, the disease being generally limited to the cellular tissue, and to the organs contained between the folds of the peritoneum, which have been noticed as characterising other chronic uterine diseases, especially dyspepsia, cephalalgia, constipation, palpitation, insomnia, debility, emaciation, evening exacerbations of fever, &c. It may terminate in resolution in the first stage, when promptly and judiciously treated; but, unlike metritis, which very rarely, in the non-puerperal state, terminates in suppuration, inflammation of the Fallopian tubes, especially when seated chiefly in the cellular tissue, generally ends in suppuration—it being purely phlegmonic inflammation.

77. d. Suppuration may be expected in the course of a few days from the commencement of the inflammation, unless checked by early and energetic treatment. The occurrence of rigor, followed by sweats, and a temporary abatement of the more acute symptoms, and sometimes a deep-seated fluctuation perceptible to the touch through the vagina, or even through the abdominal parities, indicate the disease approaching the other in character and course, that, unless there be from the first a deep-seated tumour of an inflammatory nature perceptible in one or both ovarian regions on external pressure, it is most difficult to distinguish the one malady from the other by any other method but by careful digital examination. The bladder having been emptied, the patient placed on her back, and the knees flexed, the finger should be passed into the vagina, and carried underneath and round the cervix, the left hand being firmly applied over the hypogastric region, above the pubis. By pushing the vaginal cul de sac by the finger in several directions around the cervix, especially whilst external pressure is being made, the presence of inflammation of the cellular tissue, ovaries, and Fallopian tubes, or of its consequences, is evinced by an unusual resistance on the side or sides of the uterus. The vaginal cul de sac has disappeared, and resting on the side of the cervix and body of the uterus, there is an indurated swelling, very different from the normal condition, and from what obtains on the other or healthy side, supposing disease to exist on one side only, as is most frequently the case. Pressure on the indurated parts is attended by very great pain, and there is a marked increase of the natural heat. By directing the finger around the inflammatory tumour, whilst the left hand is pressed downwards, the tumour is found to be movable and distinct from the parieties of the pelvis. This tumour being generally situated on the side of the ovaries, seems to form one mass with this organ. Hence inflammation of the lateral ligaments may be confounded with metritis even when a vaginal examination is resorted to, and an inflammatory swelling recognised. If this examination should not be satisfactory, the uterus and appendages may be further examined per annum. Dr. H. Bennet believes that a tumour formed by an inflamed lateral ligament is more intimately connected with the uterus when it is purely phlegmonic, or the result of inflammation of the cellular tissue, than when it is formed by the inflamed ovary. It is, however, very difficult to distinguish between these and acute or chronic metritis.
most frequently in the upper part of the vagina, or in the rectum. It very rarely opens into the bladder or abdominal parietes. It sometimes opens in more than one situation successively. The abscess may, however, ulcerate through the peritoneal folds of the lateral ligament, and be external and appear in the peritoneum, or in the inflammatory swelling of the uterine appendages diminishes, and as the structures return to their natural condition. “A female who has suffered inflammation and suppuration of the lateral ligaments, even in its mildest form, may be from several months to one or more years before all trace of local inflammation has disappeared, and before she can be said to be radically well.” During this period she is never quite free from symptoms of uterine irritation, or of slight exacerbations of her former malady, especially at the menstrual periods, which are often delayed or irregular; the quantity of discharge being generally scanty, seldom excessive. A leucorrhoeal discharge is always present, in various quantity. (See Puerperal Diseases, §§ 181. et seq.).

60. f. The Prognosis of this disease in the non-puerperal state is not serious as regards the life of the patient; in a few days after the first commencement of the disease it may become much more serious (see Puerperal Diseases, §§ 183, and 256, et seq.), and often most unfavourable. Apart from this state, this disease seldom terminates fatally, although it entails suffering for months or even for years. Acute metritis generally terminates by resolution, under judicious treatment (§§ 111. et seq.), without suppuration, and without consecutive lesion; but inflammation of the lateral ligaments, although apparently not a more severe disease at its commencement, and period of full development, occasional lesions which time only can remove, or which are never completely removed.

81. iv. Associations or Complications of Inflammations of the Uterus, &c.—Inflammation of the vagina and vulva may be associated with inflammation of the neck of the uterus, or even with internal or endo-metritis also; and the inflammation may commence either in the vulva or vagina, and extend to the neck of the womb, or in the latter and extend to the former. In cases of genito-rectal inflammation of the neck of the womb, it may be inferred that the inflammation commences most frequently in the vulva and vagina; but such may not always be the case; for it is not improbable that the neck of the uterus is sometimes primarily affected. In the cases, fortunately rare, in which septic or contaminating causes produce an asthenic or diffusive form of vaginitis, as well as in genito-rectal inflammation, the disease is always prone to extend from the neck to the internal surface of the womb, and even also to the uterine appendages.

82. Various derangements of the uterus, formerly considered as functional, are in most cases merely symptoms or associations of inflammation of the cervix and internal surface of the uterus, as Dr. H. Bennett has fully succeeded in demonstrating, and as becomes closed, and the tumour is resolved, the disease being brought to a close in the course of a few weeks, or of a month or two. This, however, occurs only in some cases; for in others the closing of the orifice is followed by a re-formation of the abscess; and before it again escapes, by the former or
by the mucous membrane of the cervix and vagina, from congestion of this membrane, such congestion not always amounting to disease; and of a puriform mucus, or a white or rosy transparent mucus mixed with pus, which is always the product of inflammation, and of its consequences. These three forms of vaginal discharge may be combined in chronic inflammation of the cervix. But this disease may exist without any leukorrhoeal discharge whatever, the morbid secretion being absorbed in the vagina. (See art. LUCOCONNEXAS, §§ 19. et seq.)

Amenorrhoea and other menstrual disorders are often consequences or complications of uterine inflammations. Dysmenorrhoea is very frequently a result of inflammation of the cervix uteri; and when thus associated, other disorders are often superinduced, more especially the several states of hysteria, convulsive affections, spinal irritation, &c. The changes which take place in the cervix and its canal, in consequence of inflammation or ulceration of them, are often such as occasion difficult menstruation as the consequence of contraction of the os internum, or of the canal, which often occurs. The swelling and hypertrophy of the cervix are frequently associated with this contraction, when the cervical canal itself is not the chief seat of inflammation. Dr. Simpson believes that, unless the uterine sound pass, without effort, into the uterine cavity, there is contraction of the os internum; whilst Dr. Henry Bennett contends that there exists, at the os internum, a kind of muscular sphincter, formed by a strong band of the circular muscular fibres of the cervix, and destined to close the uterus during pregnancy; and that this sphincter in the healthy state prevents the uterine sound from passing into the uterus without considerable pressure being made; and he adds, that when the inflammation of the cervix ascends as far as the os internum, or when endo-metritis exists, or the organ is enlarged by the formation of tumours in its body, or when the sound passes readily into the uterine cavity, thereby raising a sign of the presence of these diseases.

It has been considered that menorrhagia and uterine haemorrhage generally are results of active or passive congestion, or of tumours or polypi, or of malignant disease, of the womb. Dr. Henry Bennett, however, contends, and with apparently much truth as well as talent, that, in the absence of malignant disease and of uterine tumours, the quantity of blood lost during menstruation is seldom increased, for a continuance, so as to constitute menorrhagia; and that the menstrual periods are seldom morbidly approximated, unless there exist some degree of chronic inflammatory disease of the cervix, or unless menstruation be finally disappearing. Congestion of the uterus be admits to exist in menorrhagia, but it is generally the result of inflammation of the cervix; and it assumes an active or passive character, according to the amount of reaction produced by the disease on the system. If the inflammation is active and has not debilitated the patient, the haemorrhage is also active or acute. If the disease of the cervix has existed long, and has produced anaemia or debility, the haemorrhage is passive or atrophic. It is difficult to explain the reason why inflammation, granulation, or ulceration of the cervix should, in some cases, render menstruation scanty, too rare, or difficult, and in others profuse or too frequent. But the fact is proved by observation, and it may be referred to the states of innervation of the uterine canal and of its contents, and to the sympathies exerted between this very sensitive part of the uterine organs, in connection with the vascular conditions of these organs, and of the system generally. Dr. Bus- net, however, believes that, where the inflammation extends to the body of the womb, menstruation is generally scanty or retarded; whereas, when it is limited to the cervix, it is often profuse or more frequent than usual. Although this association of inflammation of the cervix uteri with disordered menstruation is so common, as now stated, still cases occur in which this latter must be referred to other pathological sources. Indeed profuse menstruation is occasionally produced by mere congestion or determination of blood to the uterus, independently of the existence of inflammation of the cervix, especially when the catamenia are finely disappearing. The association of inflammation of the cervix uteri with haemorrhage during pregnancy, in the opinion of Dr. H. Bennett, very frequently exists; the former being the source of the latter, and thus furnishing a natural explanation of the presumed menstruation of pregnant females.

That chronic inflammation of the neck and of the body of the uterus should occasion, and be associated with, sterility, with abortion, with Hystera, in its several forms; with spinal irritation, with chlorosis, and with various anomalous neuralgic and other affections, in different cases, according to the circumstances peculiar to the individual, cannot be doubted, although the relation between it and these ailments was overlooked until Dr. H. Bennett and some contemporary physicians, British and continental, insisted upon the fact of its frequent existence. Besides the complications of this disease with these complaints, the former is often associated with other lesions of the uterus itself and its appendages, as with enlargements, polypi, and fibrous tumours of the womb; with the various forms of displacement of the organ, with lesions of the ovaries; and with uterine phlebitis.

Besides the above associations, others affecting the adjoining organs or parts are not infrequent, and are to be viewed as being much more frequently consequent upon chronic inflammation of the cervix and body of the uterus, than existing as the primary affections. Inflammation of the urinary bladder, or of the rectum and sigmoid flexure of the colon, more especially of their mucous surfaces; hemorrhoids, and prolapses or fissures of the anus, and syphilitic disease of the cervix uteri, severally occur as complications of one or other of the forms of metritis. Of these the diseases of the rectum and urinary bladder are chiefly consequences of the extension of severe or protracted disease of the cervix and body of the womb, sometimes extending also to the uterine appendages, these latter, in a few instances, being the medium of morbid connection between the different maladies. It is comparatively more rare for disease of the large bowels, or of the bladder, to occasion any of the forms of metritis, than for this to cause, by the cess-
sion of inflammatory action, one or other of the former. Yet I have seen instances, in the non-
puerperal states, of metritis which had supervened on dysentery, and even of asthenic inflammation, that had extended to most of the pelvic viscera, consequent upon a dysenteric attack. Such compli-
cations do not in the least modify the frequency and fatal in the puerperal states; and in these the veins are also very commonly implicated. This complication of metritis with uterine phlebitis may occur even in the non-puerperal state, as I have seen in a few instances. In a very remarkable case of this kind, which was seen in consultation with me by Dr. R. Lax, metritis supervened upon dysentery in a married lady, aged about 35 years, and who had not been pregnant for several years. Uterine phlebitis also took place, and was followed by phlegmasia dolens. Inflammation of the excr. and pericervical tissues may extend to the uterus and uterine appendages; but this is a very rare occurrence.

87. III. Treatment of Inflammations of the Uterus and Appendages.—Much of what I have stated above respecting the treatment of the nervous and irritable states of the womb (see §§ 13. et seq.), is applicable to inflammatory action in either the cervix or body of the organ. It is manifest that, as the several inflammatory states of the uterus, whatever may be their precise seats, occur in the nervous, the debilitated, the anæmic, as well as in the puerperal and the robust, the treat-
ment, especially the general or constitutional, must depend in great measure on the knowledge, acumen, and experience of the physician, by which he is enabled to ascertain the precise peculiari-
ties of each case. A most important part, however, of the treatment is entirely local or sur-
gical; but, in the management of female diseases, no division should be made into medical and sur-
gical means, for here, as in all other departments of practice, surgery, although ancillary to, is also a part of, medicine.

88. Of Inflammation of the Neck of the Womb, and its Consequences.—There are few complaints more prone to relapse, and in its severer states more difficult to remove, than the one now under consideration. But these are not the only evils; the difficulty often of conducting the treat-
ment conformably with the requirements of the case and the prepossessions of the patient, is also a positive obstacle to success, particularly in females whose circumstances of life require exertion, or prevent them from enjoying the requisite comfort and ease, and in unmarried females. The treatment must necessarily depend upon the peculiarities of the case, with what is known or inferred as to its causes, upon the dura-
tion of the disease, and upon the alterations which have taken place in the part. But in this, as well as in all other inflammations of the uterus, the indications of cure consist, first, in subduing in-
fiammatory action and painful symptoms; and, second, in restoring the constitutional energies, and thereby the healthy state of the uterus. It often offers as great a difficulty to know when to discontinue the first indication, and when to aim at the second; for a too early adoption of means calculated to restore the health, may occasion a relapse of inflammatory action and its attendant.

89. A. The treatment before any organic les-
ions have taken place, and whilst inflammatory action is unassociated, comprises the two indica-
tions of cure just stated (§ 88.). The means which are found most successful in fulfilling the first intention, are the horizontal posture, and quietude of mind and body; injections of an emollient, refrigerant, or anodyne kind; cooling diaphoretics, or weak purgatives, warm or tepid hip-baths, local depletions, alter-
rants, and sometimes derivatives. This state of the disease, especially at its commencement, is so often unattended by severe symptoms, unless when it is associated with the neuralgic and irrit-
able conditions described above (see §§ 5. et seq.), that it seldom comes under medical care; and it is not, commonly, until either excoriations, gran-
ulations, or superficial ulcerations, very fre-
quently associated with leucorrhœa, disordered menstruations, and deviations from the natural po-
sitions of the womb, that medical aid is resorted to. In all cases, due care should be taken to ascertain the admitted and probable causes of the complaint. It will be seen, on referring to these causes (see § 10.), that certain of them can hardly be fully ascertained, although they may be inferred with a near approach to certainty; and, in some cases, they will be admitted by the pa-
tient, if inquires be made with due address. The state of general health should also receive atten-
tion, and the treatment be regulated accordingly, and with strict reference to the condition and peri-
ods of the uterine functions. In the mild cases, if they have not been of long duration, and if the cause have been only tem-
porary in its operation and not a persistent or hab-
itual vice, means directed to the improvement of the general health, to the regulation and promo-
tion of the secretions and excretions, more parti-
cularly to the prevention of febrile and urinous accumulations, aided by rest, the avoidance of sexual excitement, and by emollient and astringent or refrigerant injections according to the peculiari-
ties of the case, will be sufficient to restore the health, even without strict reference to the suc-
cession of indications of cure mentioned above (§ 90.). In severe cases, especially in those of long duration, and in those where the above means fail of affording satisfactory relief, the indications of cure stated above should be adopted, more particularly if thickening or enlargement of the cervix or any other of the lesions described as consequences of chronic inflammation be present. For these the means enumerated for fulfilling the first indication should be prescribed. For this purpose, constant reposé on a couch or sofa, avoiding very warm beds, and the upright or even the sitting posture, vaginal injections, hip-baths, local vascular depletions and a recourse to caustics, are the means of cure known in general use. But, although the chief remedies, they are not the only ones; and in all cases they should be aided by constitutional and moral treatment, by a proper diet and regimen, if indeed the local remedies be not considered as being aids only to the constitu-
tional means. To know when all these, and which, are most required, and the quanti-
ity and quality of their applications, according to the temperament, habit of body, strength, and other peculiarities of the case, that a selection of them appropriately to those peculiarities must depend upon the judgment of the physician.

91. a. Vaginal injections are often of great use.
vice, whether simple or medicated. They wash away the secretion from the inflamed cervix, and prevent the stagnation of it in the vagina and around the cervix; and the women, tending to incrustation and morbid sensibility of the parts. The frequent injection of cold water only has not only a cleansing but also a tonic and healing effect. In some cases the temperature of the water may be heightened somewhat above fifty degrees Fahrenheit. But in most cases the temperature of warm water is best, the quantity injected, or the duration of the injection, being regulated by the physician.

92. Medicated injections are either emollient, astrigent, or anodyne. Various emollient injections are of service in slighter cases, and when pain or irritation is experienced; and they may be made vehicles for anodynes. Milk and water, decoction of marshmallows, lanced tea, &c., may be used, cold or tepid. When irritation is considerable, a small quantity of borax or of any of the anodynes, especially vinum opii, tincture of henbane, or tincture of belladonna, may be added to the above. Injections also of the decoction of poppy-heads, either alone or with chamomile flowers, may be prescribed. Astrigent injections are very commonly resorted to in this complaint, especially when the discharge is abundant. In this and the above cases, the means advised for the treatment of leukorrhœa (see §§ 16, 17.), and of that state of the disease especially which I have ascribed to "inflammatory action of the mucous glands of the cervix and os uteri," (§§ 23, 24.), are quite appropriate. Of the several astrigent injections in common use, viz., sulphate of alumina, sulphate of zinc, acetate of lead, solution of nitrate of silver, decoction of oak bark, and solution of tannin, Dr. H. Bennet states that he prefers the first and the solution of nitrate of silver. The first three he uses in the proportion of a drachm to a pint of water, increasing or diminishing the strength according to circumstances. He, however, considers that injections are serviceable chiefly for cleansing the vagina, for diminishing uterine irritation, and for removing vaginal and vulvar inflammation; but that they are generally powerless to subdue confirmed inflammation of the substance of the cervix or even of the membrane lining its cavity; for he believes that their inefficacy in inflammation of the cervical canal is partly owing to the fluid not reaching the region affected; and that in inflammation of the cervix, a remedy which is only applied to the surface can scarcely be expected to subdue the deep-seated disease. When injections are prescribed, due care should be taken that they are properly administered. The patient should be on her back, with the pelvis raised, and means be used for their retention for a time in the upper part of the vagina.

93. When marked irritability and acute sensibility are introduced by inflammatory action of the cervix, Dr. Devrees recommends lukewarm flavessed tea, to be thrown up by a female syringe of sufficient size three or four times a day, and to be retained there for some time by applying a cloth to the vulva. I have more frequently prescribed, especially for unmarried females, in order to relieve the more painful symptoms, injections into the rectum, containing either the extract or the syrup of poppies, or compound tincture of camphor, or vinum opii, or tincture of henbane. In a case of remarkable severity which I attended with the late Dr. Moons, a small quantity of tincture of belladonna and preserved taint of male sponge contained in a syringe, when introduced as far as the cervix uteri, and always afforded immediate relief.

94. b. Baths.—Warm hip-baths at the temperature of 80° are occasionally of service. Dr. J. H. Bennet advises that at a temperature of 80° to 85° Fahrenheit, according to the season of the year and feelings of the patient. At this temperature they have a sedative effect, whilst at higher degrees he believes that they determine the circulation to the pelvis. In painful or difficult menstruation, a temperature of 94° to 96° is often decidedly beneficial. Dr. Gough states that he has found a partial steam-bath, used by drawing the flannel sack up to the prepuce, so as to enclose the abdomen and extremities, these being exposed to the action of the steam for half an hour every day, preferable to the warm hip-bath. Entire warm baths should be avoided in this disease, and only occasionally resorted to, and when they can be had in the patient's house or apartment. During summer a tepid bath at 65° or 70° is of service every second, or third or fourth day. Cold and shower baths should be reserved for advanced coagulacence, and are important means for fulfilling the second intention of cure.

95. c. Vascular baths. These should be chiefly local; and, with all respect for those who cultivate this specialty, I cannot agree with them in the choice of situation from which the blood should be abstracted. The situation preferred by the more recent writers on diseases of the uterus is the inflamed cervix itself; but the several difficulties in the way of the general physician, if he be averse to the manipulation which this practice involves, and if he have due regard to the feelings of the patient, and even in some cases to sentiments of virgin purity, will induce him to choose other situations than this one from which blood may in this disease be abstracted with advantage, and to have recourse to other and various means by which the end in view may be accomplished. I know that, in all cases, where this and other appliances to the neck of the womb are resorted to by physicians who practise in this especial department, the utmost attentions are paid by them to the modest feelings of the patient and to all decent and even delicate observances; but I should prefer having recourse, in the first place, to such means as cannot be objected to by the sensitive mind, or even by the captious; and leave such measures as may become matters of reproach to both the patient and physician, although most unjustly, to the necessities of the case—as a dernier ressort in practice. I may write under prejudice in favour of older modes of practice; for I have employed these and seen the benefits they afford, when judiciously employed and within what I believe but I nevertheless admit that the measures more recently had recourse to are often more quickly successful, and sometimes succeed after the others have failed.

96. Local abstractions of blood should be directed to married females, in order to remove the more painful symptoms, injections into the cervix, containing either the extract or the syrup of poppies, or compound tincture of camphor, or vinum opii, or tincture of henbane. In a case of remarkable severity which I attended with the late Dr. Moons, a small quantity of tincture of belladonna and preserved taint of male sponge contained in a syringe, when introduced as far as the cervix uteri, and always afforded immediate relief.
UTERUS — TREATMENT OF INFLAMMATIONS OF THE.

1259

patient not reduced. In these cases, or when the discharge has been scanty for some time previously, a general depletion will be advantageously premised, and more especially when the bowels are constipated, and if immersed in warm water. When pain is referred to the scum, cupping may be directed on this part. Leeches are generally most beneficial when applied to the vicinity of the anus, or the labia pudenda, or to the inner parts of the tops of the thighs just below the inguinal grooves. The quantity of blood that may be taken away, should depend upon the habit of body, the state of the circulation, and upon the severity and duration of the complaint. My objections to the application of leeches to the cervix uteri are,—1st, those already hinted at above, and particularly in respect of unmarried females; and 2d, the risk of the application of them to this part being followed by an excessive determination of blood to the organ, or by ulceration of their bites, and consequently increased irritation. It will, however, be admitted that these are contingencies which may seldom occur; nevertheless they should not be hazarded.

97. The repetition of local depletion should necessarily depend upon the effect of the previous operation, and upon the circumstances just mentioned. In cases of long continuance, when the constitution is much enfeebled, even local depletion is but ill-borne, and should seldom exceed from four to six ounces. In these its repetition is rarely attended with much advantage. But when the repetition seems required and gives relief, it should generally be to a smaller amount than the first, and be performed at a time when the return or increase of pain is anticipated. In this way it may be repeated three, or even more frequently, to the small amount now named. There are, however, instances where even a small local depletion aggravates the symptoms. These occur, chiefly, in weak, nervous, or anxious females, and in cases of long standing, or where the local derangement has been long profuse.

In this class of patients, the second indication of cure (§ 88.) should be immediately adopted.

98. Dr. Henry Bennett remarks that the application of leeches to the cervix uteri, when often repeated, is more frequently injurious than beneficial, and that the consequences mentioned above then frequently result from them. I must, however, refer the reader to his work for many judicious observations respecting the local employment of leeches in this disease. Dr. West states that, "so long as acute symptoms are present, or whenever they reappear in the chronic stage of the disorder, local leeching generally affords more speedy and more decided relief than other remedial means. The leeches should be applied to the uterus itself; not above four in number at a time; nor is it in general expedient to repeat their application above once in a week or ten days. According to the patient's state, they should be immersed in the womb within four or five days of a menstrual period; lest the regularity of that function be disturbed, either by being brought on prematurely or (which is much less frequent) by its occurrence being postponed for several days. The pain which is left behind after menstruation in some of these cases,—in those especially in which the discharge is scanty,—is, however, often very greatly relieved by the application of a few leeches as the period passes off." (Lect. p. 140.)

99. d. Cooling aperients are generally required both at the commencement, and during the course of treatment, owing to the state of the bowels and to the effects of narcosis taken from time to time. These aperients which will operate copiously once, or twice at most, and without irritating the lower bowels, are the most eligible. Castor oil, the electuary or colfection of senna, either alone or with sulphur and bichlorate of potash, will prove the most certain. In very chronic cases, or when the digestive organs and the system generally are much weakened, rhubarb and magnesia; or the compound infusions of gentian and senna, in equal parts, with tartrate of potash, tincture of hemebane, and tincture of cascara, will be found of service.

100. e. Narcotics or sedatives are often required, not only in the injections, as advised above, but also in the medicines taken by the mouth, or administered in enemata. They are most serviceable after a gentle action on the bowels has been produced. Camphor, in the dose of one or two grains, with the nitrate of potash and the extract either of hemebane, or of hemlock, or of poppy, given in the form of pill twice or thrice daily, or about ten grains of either of these extracts, dissolved in water, and injected up the rectum, immediately after the bowels have acted, will frequently afford relief when much pain is experienced. Subsequently the bitter infusions may be prescribed with tincture of hemebane, and small doses of nitrate of potash and bicarbonate of potash or of soda. These means also serve to diminish irritability of the bladder by which uterine inflammation is often attended. If deposits of the phosphates exist in the urine, small doses of hydrochloric acid, with tincture of hemebane and extract of pareira, prescribed in the infusion of calumba, or of orange peel, generally are of service.

101. f. External applications of various kinds have been recommended, as the camphor-oil liniment (one part of the oil to ten of simple camphor liniment), by Dr. West, to be applied over the sacrum by means of a sponge twice a day; in order to relieve the back-ache, plasters of opium or of belladonna, to the same situation, and with the same intention; and a small blister, or an anodyne liniment, applied over the part, when pain is urgent in either iliac region. Dr. Oldham advises the following in this latter situation:—

No. 865. B. Extracti Belladonnæ 35a.; Tinæ. Arom. (Fleming’s) Div. 1. Linimenti Saponis Comp. 35a. Mixt. Pult. Lina. Inus. In cases where pain either in the back, sacrum or iliac regions is most severe, I have found more relief procured from an embrocation, frequently recommended in this work, consisting of equal parts of the compound camphor liniment, of the turpentine liniment, with variable proportions of sweet oil and camphor, spread over the part on folds of flannel or spongioseline, than from any other application. Warm turpentine stipes are also very beneficial.

102. B. When inflammation of the uterus is attended by granulations, excoriations, ulceration, and hypertrophy of the cervix, additional means of those already mentioned are recommended, espes—
UTERUS—TREATMENT OF INFLAMMATIONS OF THE

Especially by recent writers on uterine diseases. Dr. Henry Bennett states, that the solid nitrate of silver or a strong solution, should be applied every three or four days to the inflamed mucous membrane covering the cervix, for under no circumstances must there be any ulceration nor hypertrophy of this part; and this treatment should be the first resorted to when the cavity of the cervix is inflamed, "carrying the caustic into the cervical cavity as far as it will pass." When ulceration and hypertrophy of the neck of the uterus are present, he adds that the means already advised seldom succeed in effecting a cure, unless the ulceration be recent, although they mitigate the severer symptoms; a relapse occurring in a short time. Repeated relapses, and a perpetuation of ulceration of the cervix and cervical canal, are the consequences of palliation merely, owing to the repeated determination of blood to the uterus during the menstrual periods. Should the disease not yield (and it seldom does) to the antiphlogistic means directed as above, the most efficacious treatment, he remarks, "indeed the only one that can be depended upon, is by direct stimulation of the diseased and ulcerated surface, and to modify its action so as to induce a healthy action, and, finally, cestration. This end is obtained by the use of caustics of varied strength according to the nature and extent of the disease, its chronicity, and the effects produced." "We must first subdue the sub-acute inflammatory action by emboliments, depletion, and astrigents; and then modify by direct stimulation the diseased surface, so as to substitute healthy reparative inflammation for morbid ulcerative inflammation."

103. The last part to heal in an ulceration of the neck of the uterus is that which dips into the cervical cavity. Dr. Brewster therefore insists upon the necessity of separating the lips of the os with a bivalve speculum, in a good light, and of thus carefully exploring the state of the cervical canal before the disease is pronounced to be cured. Unless this precaution be used, the ulceration may be only partially healed, and the disease cured will return and extend over the cervix in a few months. The agents recommended for the cure of disease of the cervix—for chronic inflammation, excoriations, granulations, ulcerations, with or without enlargement, induration and deviations—are chiefly the more energetic caustics, which he enumerates in the order of their powers of cauterisation:—The solution of, and the solid nitrate of silver, the mineral acids, the acid nitrate of mercury, potassa fusa, potassa cum calce, and the actual cauterity. It is obvious that a recourse to either of these requires both address and careful appliances. The nitrate of silver, acid nitrate of mercury, and potassa cum calce, are chiefly recommended by British writers on uterine diseases; these and the actual cauterity also being much employed by French physicians. For very full directions for the use of these caustics, I must recommend the reader to the works of Dr. J. Harvy Bennett, Dr. Simson, and of the other writers mentioned above; but as the directions given for the use of these means by Dr. West are more succinct, I shall give them nearly in his words; promising, however, that the able and experienced physicians now named generally have recourse to these more energetic means in the most severe and protracted cases, and when more or less hypertrophy of the cervix is associated with other lesions.

104. When the granulations on the os and cervix uteri become large, soft, very vascular, and bleed easily, they are especially in the act of forming a copious milk discharge, sexual intercourse being most painful and often followed by bleeding. Dr. West then recommends "extensive scarifications, which may be followed by the daily application of powdered alum on a piece of cotton wool, or by the introduction of a piece of cotton wool soaked in a strong solution of alum. By means of a piece of thread tied to the cotton wool, it can be removed by the patient herself in the course of a few hours, though it must always be introduced through the speculum. In the greater number of instances the state of the os uteri becomes so much improved in four or five days, that this mode of treatment may then be dispensed with, and the sedulous employment of strong astringent injections will usually suffice to complete the patient's cure. When this is not the case, the morbid condition still continues, more powerful applications may be needed. The nitrate of silver is not in general suitable in these cases, for its application is often followed by pain, and also by bleeding. The acid nitrate of mercury, both in this instance and also whenever a strong caustic is required, has seemed the most useful application; and with moderate care its employment is unattended by risk. When it is used, however, the patient must lie on her back, and one of Coxeter's bivalve speculums being introduced so as thoroughly to expose the os uteri and include the cervix, a little cotton wool must be carefully disposed all round the edge of the speculum, so as to absorb any of the superfluous acid, and to prevent it from running down outside the speculum, and thus injuring the vagina. A brush can easily be: tempered by trimming a little piece of cotton wool after it is placed in the holder, and the whole diseased surface may then be painted over with the caustic, which immediately forms upon it a white eschar. This eschar will be quite dry, and on being pressed against the part will absorb any superfluous caustic; the little strips placed around the edges of the speculum may then be removed, and the speculum withdrawn. As an additional precaution, a piece of moistened cotton-wool may be introduced up to the os uteri, before the withdrawal of the speculum, whence it may be removed in the course of a few hours by the patient. It is seldom that either pain or bleeding follows this application; and at the end of a week the eschar will usually be separated; the surface will be found to have lost its fungous character, and cestration to be commencing at its edges. A zinc lotion of about five grains to the ounce, or the black wash employed as a vaginal injection twice a day will now generally be sufficient; but sometimes the surface puts on an indolent character again, and it may then be expedient to touch it once or twice with the nitrate of silver, and I have occasionally found it necessary to repeat the application of the acid nitrate of mercury." (Lect. p. 146.) Dr. Henry Bennett employs, as escharotics, either the acid nitrate of mercury, or the potassa cum calce, fused in sticks of three different sizes, according to the peculiarities of the local lesions in the most severe and protracted cases; and gives ample directions for the use of these and other caustics, appro
principally to the circumstances of the disease. If, however, admits that cauterisation of the cervix is an operation not without danger, and must not, therefore, be either indiscriminately resorted to, or carelessly carried out. Although his own practice has been hitherto free, or all but free, from serious accidents, the same immunity cannot always be expected. Indeed, I recently learnt from M. C. that he had several cases of acute metritis and of abscesses in the lateral ligaments, the evident and immediate result of deep cauterisation. But he also tells me that he has seen the same results follow the use of the nitrate of silver and of injections; and I may mention that the two most severe instances of acute metritis that I have myself witnessed for some time in the unoperated womb occurred after the use of weak astringent vaginal injections.” (Op. Cit., p. 426.) I believe, however, when vaginal injections are followed by these severe results, that the inflammation of the cervix, or the leucorrhoea, for which these means were used, was only a part of the existing lesion; and that acute metritis, or a chronic metritis, had also existed at the same time, and was developed into the acute state by the injections.

105. *Treatment of Hypertrophy and Induration of the cervix uteri.—* These operations are the results of repeated congestion, or of inflammatory congestion and of nutritive hypertrophy. The continued existence, or repeated recurrence of inflammatory congestion gives rise to increased development of the vessels, to the exudation of plastic lymph, and to the partial organisation of this lymph, and to greatly increased size and density of this part of the uterus, often extending partially to the substance of the uterus itself, and associated with chronic metritis (§§ 62. et seq.). This lesion is commonly attended by more or less prolapsus, and often with deviations. The enlarged cervix may, moreover, be excoriated, ulcerated, or covered by granular formations, owing to the alterations of its follicles. The local means of cure are those already recommended, aided by the constitutional treatment hereafter to be noticed (§§ 106. et seq.). Dr. H. Bennett states that, “if hypertrophy resists the ordinary antiphlogistic measures of treatment, it results from the micturating influence of deep cauterisation with potassium, or the actual cautery.” Of the two he prefers the potassa, or potassa cum calce, Dr. West the acid nitrate of mercury. The actual cautery may therefore be dismissed. It should be clearly understood that these means are not intended to destroy the hypertrophied cervix, “but merely to set up an artificial eliminatory inflammation, by means of an eschar, or issue, of limited extent, established in the centre of the hypertrophied region. I do not calculate, in the remotest degree, on the destruction of tissue to which the cervix is connected; the intention is, to diminish the size of the hypertrophied cervix; but solely and entirely on the inflammation subsequently set up.” An eschar, of the size of a shilling, will answer the purpose of reducing the hypertrophy. It may be necessary to apply the caustic several times. “The ulcerations occasioned by the deep applications of the encaustic may be covered with lint, or allowed to heal by themselves. It is better, however, to touch them at intervals with the nitrate of silver, to prevent the granulations from becoming too luxuriant, and to favour the cicatrization which usually takes place in from four to six weeks.” 106. *Constitutional and general treatment.—* The constitutional treatment of chronic inflammation of the cervix and os uteri, and its usual consequences, should not be overlooked, even whilst local means are being applied. Indeed, in many cases, this treatment should precede the ovaries, or be resorted to before the cervix is only following the failure of the former. In some of the more recent works upon this and other diseases of the uterus, too little importance is attached to the recognition of the causes of the existing malady, and upon the prevention and removal of these causes, which, when removed, the salutary efforts of nature would then, of themselves, often effect a cure. In this disease, especially, as well as in the displacements and deviations of the uterus, sexual excitement and self-pollution are the most frequent causes, and these are usually allowed to continue, owing to the difficulty and delay of the subject, to ignorance of medical men of the great frequency of this vice, and to an equal ignorance of the impropriety and injurious consequences of it on the part of those who indulge in it.

107. *The constitutional treatment which I have adopted for many years, when uterine irritation, as it was then termed, or when chronic inflammatory irritation is more recently shown, was present, always was used, modified, according to the features of the case. If leucorrhoea was its prominent character, the means advised when treating of this complaint were prescribed. If the menstrual function was disturbed, the treatment recommended for the various forms of such disorder was had recourse to; and, whenever inflammatory irritation of the uterus was inferred, then means more or less antiphlogistic were advised, often conjoined with tonics, and with other remedies adapted to the peculiarities of the case. In a very large proportion of the cases of this complaint, the causes which have produced it, and the discharges which characterise it, as well as its exhausting nature and duration, have produced so much debility and irritability, and so extensive a range of sympathetic disorders,—nervous, neuralgic, cerebro-spinal, vascular, and splanchnic—as to imperatively require constitutional treatment, however much the local means above described may be required or conjoined in. What this treatment should be, or how conjoined with regimen and local measures, must depend upon the acumen of the physician, and upon the appropriate use of each of all in particular cases and circumstances. But in most cases, the patient should recline on a cool hair couch, should sleep, if married, apart from her husband, on a hair mattress, and avoid very warm feather or down beds, all sources of sexual excitement, and whett the appetite by a liberal use of nourishing food; and diet adopted, avoiding much animal food, and

...
all heating and stimulating beverages, as well as coffee and strong tea. In a severe and tedious case, for which I was consulted by Mr. Barnwell, the following pills proved of very great service:

No. 969. B Camphorae raze 3; Potassae Nitratis 3; Soda Subacetatis digit. 2; Astra. Hyosciami 3; [Naja] Typhii papaveris q. s. Micae. Fiat massa aqua, quam dividere in Pildulas xxx., quorum binas, ter in die capiat.

After these were taken for some time, they were replaced by the infusion of calumba, bicarbonate of soda, tincture of calumba, and tincture of hyoscymus.

108. In the above manner, the second indication of cure may be initiated, and may thus advance to a more tonic and restorative or nutritious treatment, so as to restore the constitutional energies, and, thereby, the healthy state and functions of the uterus. This end can be attained only by medicinal and regimenial means, both of which, however, should be carried to the utmost extent. In a few instances, I have prescribed, with marked benefit, the cod-liver oil, on the surface of a tonic infusion, with one of the mineral acids, as the compound infusion of orange peel with sulphuric acid; or the compound infusion of roses, or the infusion of cinchona with hydrochloric muriatic acid, or hydrochloric acid, or with both. In other cases, the tonic or bitter infusions or decoctions may be ordered with the alkaline carbonates, nitrate of potash, and tincture either of hembar, or of some other astringent. In cases which have been of long duration, or have been caused by self-poisoning, or which are characterised by shattered health, by pallor of the countenance, cold extremities, and more or less anaemia, the milder preparations of iron, as the tincture of the muriate, or of the acetate of iron, may be prescribed with the preparations of calumba or quassia. Dr. Davis states that he has given, in such cases, the phosphate of iron with much benefit. In some cases, especially where there is hypertrophy of the cervix uteri, the iodide of iron may be tried in the syrup of sarzex; or the iodide of potash may be taken with either the bicarbonate of potash or the solution of potash in a tonic infusion, &c.

The mixture may be found to be efficacious, and artificial menstruation may be resorted to, according to the peculiarities of the case. The Bath and Tunbridge waters, the Harrogate waters, the waters of Selzau, Geilhaus, of Enns, of Vichy, of Pyrmont, &c., have been severally recommended, and found of some service. The regimen and diet of the patient are of much importance. If married, she should sleep apart from her husband; and whether married or unmarried, she ought to avoid all causes of excitement and irritation. She should enjoy the advantages of a cool and pure air. The diet ought, whilst febrile and inflammatory symptoms are present, to be light, cooling, and chiefly carminative; and animal food should be given in very small quantity, until convalescence is advanced, when it may be taken more liberally. The beverages may consist of toast-water, barley-water, or of lemonade, or of the imperial drink. Afterwards, when recovery is far advancing, the Rheinish wine, the claret, or claret and water, &c., may be allowed. In most cases, coffee and tea are inappropriate. Cocoa, or cocoa-nibs, prepared in a simple manner, and dry-toast with little butter, should be preferred. Patients who have caused this complaint by self-poisons, have generally great appetites; and their indulgences in food and in their unnatural vice tend to perpetuate the disease, and to frustrate the treatment. For them, the diet should chiefly consist in a large proportion of vegetable and farinaceous substances, whereby the stomach may be filled, with as little excitement of the circulatory system, as possible. The mind should always be occupied by useful pursuits, and, as much as may be, by agreeable employments.

110. E. Treatment of inflammation of the cervix uteri in the unmarried, during and after pregnancy, and in advanced life. — A well informed practitioner may apply what has been already adduced to these circumstances of life; but with due care and precaution. In unmarried females, the great difficulty of treatment is in the local or instrumental part; but a recourse to it will depend much upon the severity and other peculiarities of the case. The results of constitutional treatment, which should be previously employed; the causes of the disease having been ascertained, and removed as far as possible. "The existence of pregnancy," Dr. H. Benney states, "so far from being an obstacle to the local treatment of inflammatory and ulcerative disease of the uterine neck, is a strong reason why it should be adopted and carried out without delay, unless the patient have reached the latter period of her pregnancy. If so, as the child is viable, and it is rather difficult to bring the cervix fully into view, it is as well, unless the symptoms are urgent, merely to resort to astringent injections, and to reserve all instrumental treatment until after the confinement." In the early or first six months, the local treatment, Dr. B. states, must consist in astringent injections, and cauterisation with the nitrate of silver, or the acid nitrate of mercury; the potassa cum calce being much too powerful in these cases. If ulcerative disease of the cervix exist after an abortion or confinement, he never interferes until four or five weeks have elapsed, and he then cauterises the diseased surface with the nitrate of silver. If blood be poured out from the ulcerated surface, the cauterisation invariably stops it; and then the time falls into the general category. But it should be recollected that, during lactation, the mucous surface of the cervix and vagina presents a vivid red or congested hue, from sympathy with the mammae and nipples; hence this condition should not be mistaken for inflammation, and ought not to be interfered with by treatment. The disease of the cervix in females past the menstruating age, is generally intractable; and, requires the most powerful caustics; but having been removed, the cure is permanent.

111. ii. Treatment of Acute Inflammation of the Internal Surface and Body of the Uterus. — Although the term "metritis," by local means, is supposed, especially by some French writers, to be appropriate to this state and seat of the disease, yet such means, however cautiously resorted to, cannot fail of being more or less dangerous. As this form of inflammation frequently commences in the cervix or its cavity, extending to the cavity, and is, in some extent, in most instances, to the substance or body of the organ, and in some cases also to the broad ligaments, these circumstances should always be considered, and the treatment should be prompt.
and decided. If the patient be young, or strong, or plethoric, especially if the disease has followed the suppression of the catamenia, or of other evacuation or excretion, blood should be taken from the arm, or from a vein in the feet immersed in warm water, and cooling diaphoretics and aperients applied. The warm or tepid bath, or tepid baths, may follow this, and, if the patient be severe, camphor, nitrate of potash, and extract of henbane, or extract of belladonna, or a minute dose of aconite, may be prescribed every four or five hours; or after longer intervals, if the belladonna or aconite be given. In the cases just described, local depletions—by leeches applied over the ovarian regions, or below the groins, or by cupping on the loins or sacrum—may be directed after the blood-letting, especially if this latter has not produced the desired amount of benefit; indeed in most cases the local depletions will also be required. In milder cases, and in less robust or plethoric females, the local depletions, when resorted to with decision, will generally be sufficient, especially when the internal or general treatment is judicious. Their repetition may, in some cases, be required, but this, as well as the quantity of blood which should be taken, should depend upon the severity and other features of the case. After the local depletions a tepid bath, and subsequently the terebinthinated epipeds and embrocations already advised may be placed over the hypogastric region, the fanning on which the embrocation is sprinkled having been either warmed or wrung out of hot water.

112. These measures having been employed, time should be allowed for their operation, and for the subsidence of the disease. This latter object will, however, be promoted by rest in the horizontal posture; by the avoidance of sexual excitement; by recourse to cooling diaphoretic medicines, especially the liquor ammonia acetate, with small doses of the vinum or liquor ammonii tartarizati, and some anodyne or narcotic. The only aperients allowed should be cooling and such as may not irritate the rectum: as the citrate or carbonate of magnesia; the phosphate of soda; the acetate or tartarate of potash, prescribed in emollient vehicles, or with either of the prepara-
tions of ammonia carbonisata, or calomel with opium, should not be given in metritis, as it is apt to aggravate the complaint by irritating the rectum; and medicines containing aloe should also be avoided.

113. The regimen and diet of the patient should be strictly animalogistic, and the beverages allowed ought to be demulcent, emollient, and slightly alkaline. As convalescence advances, the alkaline mineral waters of Vichy or Ems may be allowed. When the disease is neglected, or improperly treated, it may extend to the broad ligaments and ovaria, as shown above (§§ 72 et seq.), or it may lapse into a chronic state; which state, however, may be primary, although it is much more frequently a consequence of chronic inflammation of the cervix, or of the cavity of this part, or of the body of the organ, and is most frequently partial or limited in its seat, as shown above (§ 14).

114. iii. The Treatment of Chronic Metritis.—Chronic metritis, often commencing in the cervix, is also frequently kept up by the inflammation of this part and its consequences. In most cases, therefore, the disease of the cervix should be first and chiefly attacked, by the means already advised for the several morbid conditions of this part (§§ 102. et seq.). The chief local means are, rest in the horizontal posture, emollient or astringent vaginal injections, the occasional application of leeches to the cervix, before or after menstruation; and, if the patient be severe, recourse to anodyne or suppositories from which they appear most serviceable, or, if necessary, recourse to anaesthetics when the sufferings of the patient are severe. These latter, or the narcotics already mentioned (§ 93.); a recourse to belladonna, both locally and internally, or to chloroform, or to the hydrochloric ether, or hydrocyanic acid, &c.; the introduction of opium or other anodyne injections or suppositories into the rectum or vagina; and the external embrocations and epipeds already advised (§ 101.), are the chief means by which we may hope to remedy this state of disease. In obstinate and protracted cases M. Gessner and others have had recourse to an issue formed above the pubis, keeping it open for some months. In a severe and prolonged case, which I attended with Mr. Flockton, many years before the appearance of this recommendation, I directed an issue to be made below both groins, with the most complete success.

115. The enlargement, partial or general, of the cervix and body of the uterus, in protracted chronic metritis, suggests not merely the local measures noticed above for reducing this enlargement, and the other evils which usually attend it, but also such other general or constitutional means as are sometimes found of service in removing other states of enlargement, morbid deposition or growth. These means may not be of much avail in the disease now under consideration; but the most important of them may be so employed and combined as to very considerably improve the general health, which is usually injured by the local malady, and to alleviate the sufferings of the patient. These means are, the bi-chloride of mercury, the preparations of iodine, the iodide of arsenic and mercury, the fixed alkali and their salts, and the preparations of sarza, severally but separately conjoined with tonics, anodynes, or narcotic; or, in these principal medicines I proceed to offer a few remarks, in respect of the treatment of chronic metritis and its complications, especially when characterised by enlargement of any part of the uterus.

116. The "bi-chloride of mercury" is beneficial or injurious, according to the manner of prescribing it. It may be of service even when the constitution has been very remarkably injured by this protracted malady. But it should in most instances, and in these especially, be prescribed either in the fluid extract of sarza, or in the compound tincture of cichorius, or in the decoction or in mixtures, consisting chiefly of all these, with or without some narcotic, as the tincture of comium, or of henbane, &c., or with a few drops of the tincture of opium, or with the compound tincture of camphor, if the medicine should have too relaxing an effect on the bowels. This substance, thus taken, in doses varying from the sixteenth to the eighth of a grain, has a very salutary tonic and alterative effect, even although the hypertrophy of the uterus may not be much, or even though its size may be reduced by it.
117. The preparations of iodine are of service only when given in small doses, and continued for a considerable time. The iodide of potassium I. have, in these cases, prescribed in doses of one to two grains, thrice daily, with the bicarbonate of potash, or liquor potass, or Brandon's alkaline solution, in a tonic infusion or decoction, or as light the presence of the bichloride of mercurous and local blood-letting. If, however, these means fail in preventing the formation of pus, or in procuring the absorption of whatever may have already formed, the purulent collection will find its way to the exterior, by the vagina, rectum, abdominal paries, or bladder. In these circumstances, we can only endeavour to control the symptoms, by means suitable for this purpose, to assist nature in throwing off the morbid formation, in the direction to which she points, to support the constitutional powers of the patient, in order that this end may be attained, and to palliate the more immediate symptoms which present themselves. The treatment advised for chronic metritis is suitable for this stage of the disease. If the abscess open into the urinary bladder, the means required will be suggested by the state of the urine. If this excretion continue acute, the local irritation of the bladder, with its attendant symptoms, opiates, or other anodynes, will be most serviceable; and tonics, restoratives, the preparations of buchu, or persea, &c., be also required. If the urine become ammoniacal, or even neutral, the mineral acids, with cinchona, quinine or other tonics, opiates, &c., should be exhibited. If the abscess open in the rectum, or flexure of the colon, the consequent tenesmus, and other dysenteric symptoms, will subside after a short time, if, with restorative and anodyne medicines, anylaceous or mucilaginous injections, with opiates, be administered. The burning of the abscess into the vagina terminates favourably if the constitutional powers be supported, and the unpleasant symptoms palliated, the vagina being occasionally washed by a lotion of tepid or of cold water. If the abscess point externally, tonics, with alkalies, and attention to the excretions, are necessary; and as soon as fluctuation and redness of the part appear, an opening, made by the lancet, should not be delayed. Afterwards, the powers of life should be duly supported; and the ingress of air into the cavity of the abscess carefully prevented, whilst the accumulations of matter should be prevented or moderated by gentle pressure; and whenever any ecchymosis occurs, it should be discharged.

121. Treatment of Inflammation and Abscess of the Uterine Appendages.—At an early stage the treatment of Inflammation of the Uterine Appendages is the same as that advised for Acute Metritis (§ 111.). But in order to prevent suppuration, which is very much more liable to occur in the former than in the latter, more prompt and more decidedly antiphlogistic measures are required. At the same time, general and local blood-letting. If, however, these means fail in preventing the formation of pus, or in procuring the absorption of whatever may have already formed, the purulent collection will find its way to the exterior, by the vagina, rectum, abdominal paries, or bladder. In these circumstances, we can only endeavour to control the symptoms, by means suitable for this purpose, to assist nature in throwing off the morbid formation, in the direction to which she points, to support the constitutional powers of the patient, in order that this end may be attained, and to palliate the more immediate symptoms which present themselves. The treatment advised for chronic metritis is suitable for this stage of the disease. If the abscess open into the urinary bladder, the means required will be suggested by the state of the urine. If this excretion continue acute, the local irritation of the bladder, with its attendant symptoms, opiates, or other anodynes, will be most serviceable; and tonics, restoratives, the preparations of buchu, or persea, &c., be also required. If the urine become ammoniacal, or even neutral, the mineral acids, with cinchona, quinine or other tonics, opiates, &c., should be exhibited. If the abscess open in the rectum, or flexure of the colon, the consequent tenesmus, and other dysenteric symptoms, will subside after a short time, if, with restorative and anodyne medicines, anylaceous or mucilaginous injections, with opiates, be administered. The burning of the abscess into the vagina terminates favourably if the constitutional powers be supported, and the unpleasant symptoms palliated, the vagina being occasionally washed by a lotion of tepid or of cold water. If the abscess point externally, tonics, with alkalies, and attention to the excretions, are necessary; and as soon as fluctuation and redness of the part appear, an opening, made by the lancet, should not be delayed. Afterwards, the powers of life should be duly supported; and the ingress of air into the cavity of the abscess carefully prevented, whilst the accumulations of matter should be prevented or moderated by gentle pressure; and whenever any ecchymosis occurs, it should be discharged.
Mr. Acton in his excellent work on "Diseases of the Urinary and Generative Organs in both Sexes," has treated this subject in a chapter on "Blepharorrhagia of the vulva, urethra, vagina, uterus and ovary," but he views the disease as in all respects the same as inflammation of these parts occurring independently of a specific constitutional cause. He regards the inflammatory condition—that it is an acute form of inflammation there can be no doubt, but that it is more severe, more disposed to extend to the uterine cavity and appendages, than common inflammation, whether acute or chronic, commencing in the cervix uteri and produced by other causes, would appear from the cases I have treated. All these cases were of married women, the gonorrhoeal infection having been communicated to their husbands; and, in all, the infection was most manifest, the patients not being previously subject to any leukorrhoeal discharge, and was followed by most severe symptoms of inflammation of the womb, and by the extension of the inflammation still further, as stated above. On this subject Mr. Acton remarks that, "a female suffering under uterine blepharorrhagia may be seized with shivering and a feverish state of the system; vomiting may commence together with pain referred to the iliac fossa, where more or less tension may be present (in no way resembling the superficial pain produced by pertonia); but if the finger be carried up the cul de sac of the vagina, and the patient desired to turn upon the opposite side, pain of a most acute kind will be felt. The blepharorrhagia may cease for the moment, one ovary may be attacked only, or both simultaneously, as in epidemicymis; reversion will explain the partial cessation of the discharge. Lastly, we believe that a great number of ovarian drop-sios may result from a chronic inflammation of that organ, the consequence of such complications," (Op. cit. p. 308.). I can fully confirm the correctness of this last remark by a recent case of ovarian drop-sis which occurred in the wife of a very eminent man, and was the ultimate lesion which followed gonorrhoea communicata by her husband, and which led to the commencement, and is still, under my professional care.

123. i. SYMPHILITE ULCERATION OF THE CERVIX UTERI.—Both Dr. Henry Bennet and Mr. Acton agree in considering symphilite ulceration of the cervix as a rare occurrence. The latter remarks that, in the vagina and os uteri, the circumstances favouring contagion do not often occur, for if the contagious pus of chancre reaches as far, it is generally deposited on a layer of mucus, which protects the membrane beneath. He concludes that "ulcerations of the neck of the uterus are in ninety-nine times out of a hundred merely simple affections, the result of acute or chronic inflammation, very intractable in ordinary treatment, and will persist an almost indefinite time, unless we employ local applications." True syphilite ulcers of the cervix uteri are described by Mr. Acton as differing from all other ulcers of this part. "They are small, covered with a chamois leather secretion, which is difficult to remove, their edges are distinct; they look as if a portion of mucous membrane had been punched out of the os uteri, and inoculation has shown that they were true chancre, situated on this unusual position." (Op. cit. p. 292.)

124. III. The treatment of these specific diseases of the uterus is not different from that advised for the affections above described.—A. As respects gonorrhoeal inflammation of the womb and its appendage, the means are the same as those advised for the more acute inflammations of these parts; the chief modifications consisting in a more prompt and decided use of these means as the symptoms are very severe. In many cases, the inflammation of the vagina is so severe, and the swelling of both it and the vulva so great, as to prevent a recourse to many of the means already advised, especially at an early stage, injections of an emollient and anodyne kind being first prescribed, and sedatives, demulcients, refrigerants, and narcotics internally. In other respects, and as the disease continues or is prolonged, the remedies already recommended for inflammation of the uterus and its appendages, should be administered appropriately to the peculiarities and complications of individual cases.

125. B. The treatment of syphilitic ulceration of the cervix consists in the use of the acid nitrate of mercury locally, as directed above (§ 104.), and in the employment of the constitutional means indicated by the existing state of the case, and by the appearance of any signs of Venerial Cachexia (see that article).

126. V. DISPLACEMENTS OF THE UTERUS.—The womb being suspended in a cavity more or less capacious, but liable to alterations in the extent of its capacity; its supports being not only yielding, but also admitting of considerable mobility; its manifest changes in size and position during pregnancy; and its movements during coition, and the veneral orgasm, are circumstances requiring consideration whilst endeavouring to describe and explain displacements of the uterus, as well as to remedy these evils. The causes of these disorders are often manifest, but in some cases they can only be inferred from insufficiently conclusive evidence. It is not to be disputed, that an enlargement of the organ will favour its descent; that muscular efforts, especially lifting heavy weights, will have the same effect, even independently of enlargement of the womb. In an enlarged uterus, the vagina and ligaments are relaxed by childbearing, leucorrhoea, &c.; and that partial or general enlargement, the pressure of loaded adjoining viscerae, too severe or prolonged exertion, especially during the menstrual period, falls on the back, hip, connexions of the trunk of the body, &c., will occasion either that or other forms of displacement.

127. It should not be overlooked that, in the great majority of instances of displacement of the womb, other lesions of the organ, either inflammatory or structural, are associated with the displacement. This circumstance is of no mean importance both in recognizing the cause, conditions, and relations of displacement, and in regulating the treatment and regimen of the patient.

128. i. DESCENT OR PROLAPSE OF THE WOMB is the most common form of displacement; and proceeds from increased weight of the organ, or from impaired tone of its supports.—A. Dr. West has considered this lesion with reference to its grades, and divided it into the first, second, and third degrees of prolapse. **In the first degree the organ is merely lower than natural, but still preserves its proper direction, its axis corresponding
with that of the pelvic brim, and this, even though it should be so low that its cervix rests upon the floor of the vagina. In prolapse of the second degree, the uterus is situated with its fundus directed backwards, its orifice forwards, so that its long axis corresponds with the axis of the pelvic outlet. In prolapse of the third degree, or as it is often termed, providentia of the uterus, the organ lies more or less completely externally, hanging down beyond the vulva, though it generally admits of being replaced within the vagina, if not of being altogether restored to its natural position. It is obvious that a due recognition of the circumstances, both physical and pathological, favouring and causing this displacement, is of the greatest importance in preventing and removing the different grades and complications of it observed in practice. The womb is not merely suspended by the duplications of the peritoneum within which it is contained, but it is also poised upon the vagina, which, in the healthy virgin state especially, furnishes it very considerable support. The curved direction of the vagina, the connection of the organ, appendages, and vagina with the adjoining viscera, with the pelvic antrum, perineal fascia, &c., also aid in supporting the uterus in its situation.

129. These combined supports, however, may severally be relaxed or overcome during the epochs of life following puberty. In the virgin and unmarried state, leucorrhoea, menorrhagia, anaemia, exhausting discharges, and frequent excitement of the venereal organ by masturbation, severally tend to relax the tone of the parts which support the womb in its natural position. During the sexual organs its mobility is manifested to the greatest natural extent, its descent often occurring in various degrees, without becoming greater than is consistent with the healthy function; but it is obvious that, when unnaturally produced, the healthy condition is at last exceeded, and that more or less displacement is apt to occur, especially as the same cause practised to excess tends remarkably to relax the tone of the parts upon which the healthy position of the organ depends. In the married state, as well as sometimes in the unmarried, although more remarkably and much more frequently in the former, enlargement and greater weight of the womb, and the stretching, relaxation, and other changes of the supporting parts consequent upon abortions, child-bearing, difficult labours, and puerperal diseases, very materially predispose to the descent and other displacements of this organ. If, in these circumstances, the erect posture be too early resumed after delivery or abortion, if falls or concussions of the trunk of the body be experienced, or if violent muscular efforts be made, as in lifting or carrying heavy weights, a greater or less descent, or hernia of the uterus is apt to take place. Aged and emaciated females, married or unmarried, are most frequently liable to this displacement, sometimes in its utmost extent, owing to the enormous size of the abdominal organs adorning the vagina and vulva, especially when the exciting causes just mentioned have occurred.

130. Descent of the uterus, even in its first and second degrees, is very commonly attended by some degree of retroversion; and this state is often, as well as the descent, increased by constipation of the bowels; the hardened faces, in the efforts at defecation, augmenting the extent of both states of displacement, by pressing upon the fundus of the uterus. Dr. West justly remarks that "the close connection between the cervix uteri and the neck of the bladder is a temporary obstacle to the descent of the former; while, at the same time, it favours the retroversion of the organ; but, if at length this yields, the urine accumulating in the bladder distends its fundus and the vaginal anterior wall into a pouch which draws down the uterus in front just as the prolapse of the rectum drags it down behind; and the organ now soon comes to lie beyond the external parts; the case being thus converted into one of providentia uteri, or of prolapse in the third degree." (Lect. p. 156.)

131. This displacement of the uterus is, in the course of time, followed by still further changes. The neck of the womb, being the first part protruded, and the most exposed to irritation, becomes more and more hypertrophied, and often excoriated; the enlargement being both in length and thickness. The protrusion of this part of the organ is partly due to inordinate growth, its thickness being sometimes equal to, or even greater than, that of the waist. The lips of the vagina become enlarged with the rest of the organ, and the transverse opening formed in women who have had children, is converted into a wide opening situated deeply between projecting lips, whose surface is irritated, excoriated, vividly red or granulated, and covered by an albuminous secretion. The prolapse beyond the vulva may continue only in a partial state for years, the fundus and a portion of the organ remaining within the pelvis, while the neck and the lower part are external. In this state, the organ may still be replaced without difficulty, especially when the prolapse has followed soon after delivery at the full period, the pelvic floor being sufficiently yielding in most instances. In the course of a variable duration, a partial descent is often followed by a complete protrusion of the organ, "the vagina becoming inverted, and forming the outer walls of a tumour, the inner part of which the womb is situated. So long as the providentia is incomplete, this tumour is somewhat pyriform in shape, its base being directed upwards; but afterwards, as it increases in size, it assumes an oval form, owing to more or less of the bladder being drawn down into it in front, and of the rectum also, in many cases, behind. Its bulk is also further swelled, in numerous instances, by the small intestines sinking down into the sac, and thus adding to its size until it equals or exceeds that of the adult head." 132. In these cases, the uterus itself forms only a comparatively small portion of the large external tumour. The susceptibility of the organ, and the disposition to hypertrophy, are much diminished by constant and complete prolapse from the pelvic cavity. "The bulk of the tumour, and the difficulty of its replacement, depend chiefly upon two causes. Of these, the one consists in the enormous size of the abdominal organs adorning the vagina and vulva. Not only does their mucous membrane lose its ordinary character and become covered by a layer of cuticle like that of the skin, to protect it from the various sources of irritation to which it now becomes exposed, but the walls themselves attain a thickness of as much as half an inch, and present a dense muscular structure.
The other cause of the bulk of the tumour, and of the difficulty of replacing it, arises from the presence of the intestines in the sac, which seldom reside there long without inflammation of their peritoneal covering being set up; not of so acute a character, indeed, as to produce formidable symptoms, nor even as always to call for treatment, but most frequently, and least of all in other, and tying them firmly to the interior of the sac." This latter cause of difficulty in attempting to return a long pendent uterus, should not be overlooked, for, even though no intestines have descended into the external tumour itself, chronic peritoneal inflammation may agglutinate them to each other, or to the walls of the pelvic cavity, and thus oppose the replacement of the womb.

133. B. The symptoms of prolapse of the uterus.

—The symptoms may be severe in some cases, and hardly experienced in others. In the unmarried, and when occurring suddenly, prolapse of the uterus is attended by much more severe or acute symptoms than when it occurs in married females after miscarriage or delivery, or when it takes place slowly. When it is caused in single females after prolonged dancing or riding on horseback, the symptoms are generally rapid and severe; and even in married females who have borne children, and have subjected themselves to these causes, the descent is usually rapid, and the symptoms are also severe, but the prolapse is generally greater than in the single. The sensation most frequently experienced is that termed "bearing down," or of falling down of the pelvic viscera. This feeling is augmented by lifting weights, or by bodily exertion; and then it is often attended by a sharp pain. Defaecation is difficult and painful, and is followed by some degree of tenesmus. Pain in the direction of the vagina, when sitting down, especially on a hard seat, pain in the back and low in the sacrum, and a very frequent desire to pass water, are always experienced. Leucorrhoea is often complained of, and the estomach are either profuse, prolonged, or too frequent. The digestive organs are soon affected or less disturbed, the bowels are constipated, and the general health suffers; and as the prolapse becomes chronic or prolonged, the cervix and even the body of the uterus become hypertrophied.

134. External prolapse, or procidentia uteri, generally follows the internal prolapse, or that in which the uterus and cervix still remain within the external parts; and usually takes place gradually. It is favoured by emaciation or the absorption of the adipose substance in the vicinity of the vulva; and it occurs most frequently after a too early change of position after parturition or miscarriage, or being by accident, or walking about, after these occurrences. In these circumstances especially, sudden, unusual, or great exertion, or straining at stool, or lifting weights, may occasion procidentia suddenly; and the symptoms may then be severe. As the cervix, the lower part of the body of the organ lies nearly or constantly without the external parts. After the protrusion, the sensibilities of the uterus become blunted by the exposure, and the vaginal leucorrhoea subsides. But, as the procidentia increases, the relations of the uterus with the adjoining organs and parts are changed. The urinary bladder and urethra are more particularly implicated, occasioning dysuria, a frequent desire to empty the bladder, or incontinence of urine. The rectum is also affected so as to render defaecation difficult, cools to each of the small intestines into the pelvic cavity, and the excoriations, thickening, irritation and ulcerations of the exposed parts, owing to exposure to the air, and to the dribbling of urine, and to other contingent occurrences, increase the sufferings of the patient. With the complete prolapse, hypertrophy of the organ increases, more especially its cervix and the lips of the os uteri, which, moreover, become ulcerated to a considerable extent, the cavity of the cervix being drawn apart, so as to become open or gaping, the ulcerations extending into it. In many cases of internal prolapse, pregnancy takes place rapidly, but this period is often one of considerable suffering. If the prolapse be slight, pregnancy generally cures it, as the uterus rises in the pelvis with the advance of gestation, especially if cure be taken, and the patient remains in a recumbent position long after delivery. When the uterus is either pressed by an external or internal impregnation rarely takes place. In the former case, the sufferings of the patient are greatly increased by impregnation; and miscarriage usually takes place, the organ being unable to rise into the pelvic and abdominal cavities. "In some few instances, however, pregnancy runs its course undisturbed, in spite of a great degree of prolapse; and cases are on record in which the uterus has descended further and further, until a great portion of it hung down between the thighs; but the development of the fetus has, nevertheless, gone on in this unnatural position; and others still stranger, in which coitus has been practised immediately through the os uteri, and impregnation and undisturbed gestation have followed in spite of the existence of irreducible procidentia,"

(Westy, Lect. p. 172.)

185. C. Treatment.—The causes which tend to oppose the return of the organ are those causing prolapse of the uterus, have been explained above (§ 132.); and the same causes, although operating in a less degree in simple or internal prolapse, often prevent the complete restoration of the womb to its normal position. The first object, in respect of treatment, is, to ascertain the causes of prolapse, and the circumstances connected with its occurrence and progress; for the means of cure or of palliation must be directed accordingly. Carefully avoiding the causes of prolapse (§ 126. et seq.), the patient should strictly observe rest and the recumbent posture; preserve a gently open state of the bowels, and have recourse to stringent injections, and the cold hip-bath. When the womb is much enlarged, as well as prolapsed, the measures advised above for the enlargement (§§ 115—120.), should be adapted to the peculiarities of the case. It should be recollected that there is always a tendency towards the descent, even when the womb has regained its proper position, upon the recurrence of the menstrual period. If, therefore, due care and proper precautions be not taken on the accession and during the course of this period, the descent may return; and each return will be more severe, etc.
136. As respects a recourse to mechanical support, to order to keep the uterus in situ, as well as regards a selection of those supports, I must refer the reader to directions contained in Dr. West's very able and instructive Lectures, and be contented with a reference to the more general principles and directions he has there adduced:—1st, In cases of slight descent of the uterus, resulting from a general loss of tone in the parts, or from some temporary or accidental cause, as excessive fatigue, over-exertion; 2d, In cases where the descent of the womb is still comparatively recent, and is due to the persistence of puerperal hypertrophy owing to imperfect involution of the organ (§ 602) after abortion or labour; 3d, In cases where uterine disease, of whatever kind, was the occasion of displacement of the organ, such disease being still in a stage requiring treatment. In these several circumstances, mechanical support of the uterus is not only necessary, but necessary and desirable. On the other hand, mechanical means of some kind or other are required.—1st, In all cases of external prolapse or procidentia; 2d, In cases of long standing prolapse of the second degree, associated with much relaxation of the vagina, and consequent weakening of the uterine supports; 3d, In all cases of extensive laceration of the perineum, and for a similar reason in cases of prolapseus in the aged; 4th, In cases of less degrees of prolapse attended by extreme suffering; 5th, In all cases of considerable prolapse of the vagina, with or without descent of the rectum or bladder, and in all cases in which the uterine prolapse is secondary to any of those other forms of displacement. It is unnecessary here to describe the several kinds of support or contrivances which have been advised. They are either external or internal, according to the manner of their employment. They are well described in Dr. Wray's work just referred to, where other directions are also given for their use.

137. These contrivances for the relief of prolapse of the uterus or vagina, are merely palliative; they bring about, however, a cure in some cases, by preventing any increase of the displacements, and by giving time for nature gradually to remove them, more especially in slight or recent cases. But in cases of long standing, and in those in which the descent is considerable or complete, there is much uncertainty in their results. Therefore operations have been devised for contracting the orifice of the vulva, and the prevention by such means of external prolapse. In cases of lacerated perineum, the restoration of this part by an operation is obviously the most successful mode of curing a prolapse; and it has been often successfully attempted. But in cases where the orifice of the vulva is relaxed, or is widened by the uterine descent, means have been taken by Dr. Frick, Mr. Brown, M. Gerardin, M. Langan, and Dr. Kennedy, for its contraction, with various degrees of success. These means will readily suggest themselves to most medical men. A further notice of them does not fall within the scope of this work.
gravid uterus; whilst sudden efforts, or violent exertions, falls, concussions of the trunk, will concur with these and other causes or circumstances, as with the catamenial period in the non-gravid, in producing this form of deviation, namely, retrusion. Previous delivery, miscarriages, difficult menstruation, congestion of the uterus, intemperance, sexual indulgence, and increased secretion of blood to the organ, will also predispose to, or even cause, this occurrence, as well as some other conditions hereafter to be noticed (§ 142. et seq.).

141. B. Anteversion of the non-impregnated uterus was, only a few years ago, considered to be a rare occurrence. I find in the notes of a case, which I saw with Mr. Hoyland, in 1843, that I remarked that one to have been only the first of which I had seen, and that this case was most probably owing to adhesions of the fundus of the uterus, as the lady had been some considerable time previously the subject of pelvic peritonitis. Madame Boivin had, however, many years previously pointed out attacks of circumscribed peritonitis as a not infrequent cause of abortion. Without such adhesions it is difficult to account for the occurrence of anteversion, owing to the relative position of parts; and there is much reason for inferring, with Dr. West, that many of the cases believed to be those of anteversion were actually cases of anteflection, the fundus of the organ having been bent forwards on its cervix. But even in this case, the explanation of its occurrence is not easy. In married females, however, some allowance should be made for the mechanical effects of sexual intercourse in connection with the venereal organ in the female.

142. C. As respects the deviations usually termed version and flection, Dr. West remarks 44 that in the greater number of cases of alleged version of the womb, either forwards or backwards, the organ is really flexed or bent upon itself; and further, that not infrequently the two conditions co-exist, the whole womb being thrown more forwards or more backwards than natural, while in addition the body of the organ is bent upon its cervix. As far as the symptoms are concerned to which they give such various degrees of deviation present but little difference.

143. As to the point of flection of the uterus, whether backwards or forwards, Dr. West agrees with Professor Vinckow of Berlin, in considering it to be the junction between the body and neck of the womb, or, in other words, the spot corresponding to the internal os uteri; and that the flection is owing to the anatomical fact, that, while the neck of the womb is firmly connected with the posterior and lower part of the bladder, its body is perfectly moveable. As to the comparative frequency of the two forms of deviation, Dr. West states that his notes furnish the particulars of twenty-six cases of retroversion and retroflection, and of nine anteversion and anteflection. M. Vallesi, however, gives thirty-five deviations of the uterus forwards, and thirty-three backwards; and Dr. Mayer, of Berlin, sixty-three cases of the former and forty-six of the latter. The frequency of adhesions, and of other indications of previous inflammation, as a cause of deviations of the uterus, is shown by the statement of Dr. West, that he met with these lesions of the womb, its appendages, and the vicinity, in twenty-two out of sixty-six cases, in which he examined the uteri of women who had died of some other than uterine disease.

144. Protracted flexion of the uterus may be expected to be followed by further lesions. These are narrowing of its cavity, at the point of flection especially, and atrophy of the part of the womb on the side increased deviation, the flexion occurs, thereby rendering it permanent.

145. The cervix is very generally more or less diseased in all the forms of deviation of the uterus, presenting the several states of lesion described above as being seated in the cervix externally and internally—these being chiefly indicative of inflammatory irritation or action, granulations, excoriations, ulcers, enlargement of the cervix, and an open or gaping state of the os and cervical cavity, enlargement of the posterior lip of the cervix, &c. (see § 27. et seq.); these severally, or two or more of them jointly, being very frequent concomitants of deviations of the uterus from the normal state. That these lesions of the cervix are not always consequences of the deviations, my experience induces me to believe, and to infer that Dr. H. Bennett more correctly attributes the deviations to pre-existing disease of the cervix. It appears that those alterations of sensibility of the cervix associated with more or less irritation or chronic inflammatory action, and with the several consequences of sexual excitement, leucorrhoeal discharges, disordered menstruation, and their numerous and ever-varying sympathetic affections, are more likely to give rise to deviations of the position of the uterus, and not only to the deviations already noticed, but also to others, consisting of obliquity of position, or to lateral deviations (which I believe to be the most frequent of any, and to be generally of temporary duration), when unconnected with disease of the ovaria and the broad ligaments, than that these deviations of the womb from its natural position should occasion disease of the cervix. It may be readily allowed that any pre-existing disease in this part may be aggravated by lesions of position; but that the former is a consequence of the latter, requires further proof; and that the positive evidence furnished of a different succession of lesions would require to be previously disproved.

146. D. The symptoms of deviations of the uterus have been subjects of contention even with those who have taken female diseases under their special protection. Now, therefore, shall those who get only occasional glimpses of uterine diseases decide, when so very opposite views are entertained by the professors of this specialty? The former are, however, the judges in the cause; the latter are the partisans or advocates of their respective doctrines. Thus it is stated, by a very recent and able writer on these diseases, that "the symptoms are by some described as being both numerous and characteristic, and the appropriate treatment is by them alleged to be both simple, safe, and successful, while others deny that the mal-postions, taken by themselves, produce any symptoms of the latter. The theory of exposed treatment, while attended by very considerable risk, is wholly inadequate to the removal of the evil which it is intended to cure. Each of these opinions, too, is maintained by men equal in the eminence of their position, in their practice."
experience, and in their good faith." (Op. cit. p. 206.) This statement is borne out by the discussion on this subject reported in the "Bulletin de l'Académie de Médecine" for 1853-4 (vol. xix. pp. 778—797), and is there fully and remarkably illustrated.

It is very obvious to the student of human nature, that, however well informed individuals may be in their especial department, and however eminent in popular estimation, as long as occurrences, morbid actions, and their consequences, vary so as to give rise to modified or different signs, phenomena, or symptoms, and to develop modified or altered features or aspects, so long will the observers of these see and believe certain of them in preference to, or to the neglect of, the rest, and thus form one-sided views, which the very majesty of their position, in either professional or popular opinion, or both, will not admit of being impugned, and for which they will contend with biased judgments, even in opposition to the most obvious truths. Now, as one of the professed judges in such matters, and having no preconceived opinions as regards them, I venture to state, that the symptoms vary, in severity and number, with the predisposing and excitant, with the sensibility and irritability of the sexual organs themselves, and of the constitution, with the existing deviation and its extent, with its several associations with disease of the cervix and its consequences, with the states of the natural and morbid uterine discharges, and with the several complications which deviations of the uterus present with the adjoining viscera. Hence it may be inferred, that the slighter deviations, which have taken place slowly or gradually, in females evincing but little susceptibility or irritability, and which are not associated with marked disease of any part of the uterus, or of structures connected with it, may not occasion any disorder calculated to excite anxiety in the patient, or to require medical advice, and yet may exist for a long period, or may disappear altogether, from the efforts of nature or from changes in the female economy or in the constitution. But deviations of the uterus to a considerable degree, even more so, are to be regarded as arising from well-recognized causes, and when associated with other uterine lesions, or with diseases of adjoining parts,—and even when existing simply in susceptible, sensitive or irritable females, married or unmarried, more especially in the latter when masturbation is suspected,—then will very generally occasion symptoms which, if they do not prove, should at least induce the physician to ascertain its existence or non-existence by an examination. That the symptoms are often, however, more or less equivocal, or that they may frequently accompany other lesions of the womb, must be admitted, but a vaginal examination readily solves the difficulty, and evinces the true nature of the complaint. The symptoms usually present in uterine displacements or deviations are, excessive, painful or difficult menstruation, leucorrhoea, discharge, pain in the pelvis generally, and most severe in that part of the pelvis towards which the fundus uteri is turned or flexed, pain and difficulty in defecation and micturition, constipation, frequent calls to pass urine, or sometimes retention of it, and sterility. According to the temperament and habit of body of the patient, various sympathetic disorders may be induced by uterine deviations, chiefly affections of the digestive organs, as nausea or retching on the accession of the catamenia, hysterical symptoms, pain under or in the mammae or in the spine, neuralgic pains in the limbs, &c.

148. As respects this disputed question, Dr. West justly remarks that, although cases occur, on the one hand, that flexions of the womb do not, of necessity, give rise to any distress, and, on the other, that the removal of a flexion of the organ may not be followed by relief of the patient's sufferings, the fact still remains, that displacement of the womb is in very many instances attended by various uterine ailments not experienced before its occurrence. Here, however, the question suggests itself,—Are the sufferings of the patient due simply to the displacement, or to the morbid condition with which the displacement is associated, or to the two causes conjoined? Dr. West answers this question by stating that "there are circumstances which appear to favour the opinion, that, in the majority of instances, the symptoms are due not to displacement alone, but to dis-placement accompanied by some other morbid state of the womb." This opinion is confirmatory of that already given by Dr. Curney, that the deviation is nearly always a consequence of chronic inflammation of the cervix, is associated with the cervical disease to which the sufferings of the patient are mainly due, unless in extreme cases of displacement. For some remarks on the diagnosis of versions and flexions of the uterus, and on the use of Dr. Simpson's uterine sound for this purpose, I must refer the reader to Dr. West's lectures, and to the other recent works on uterine disease. There can, however, be but little difficulty in the diagnosis between such deviations and tumours in the uterus, for which they can hardly be mistaken.

149. E. The treatment of deviations of the uterus has been a matter of dispute among modern authorities on uterine diseases. Certain of these contend, that the lesions of the uterus to which the deviations are due, and to which the symptoms are chiefly owing, should be made the objects of treatment, while others place the uterus to its right position, and to maintain it there by mechanical contrivances. Schweghauer, Schmitt, Oldham, and others, have supported the former treatment, whilst Dr. Simpson, Velpeau, Kirsch, and Vallet, have resorted to the latter. These contrivances have undergone various alterations in the hands of the several authorities who have had recourse to them. From what I have seen of cases in which they were employed, and from the opinions of M. Dubois and Professor Scanzon, as stated by Dr. West, I believe that, although they may be successful in some
cases, under the care of able and careful practitioners, they are attended by no small risk, as respects the uterus, its appendages, and peritonæum; and that the return of the displacement is very frequent after the mechanical contrivance is removed. At a recent discussion in the Academy of Medicine, Dr. Poupart stated that he had himself treated upwards of twenty cases by means of the uterine supporter, which in some instances was worn for several months, but that the displacement reproduced itself within a very short time after the removal of the instrument; and that he had made a similar observation in the case of many patients who, having been thus treated by M. Valette and Dr. Simpson, had been dismissed by those gentlemen as cured.

Professor Scanzoni remarks that "the observation of fifty-six cases of flexion of the uterus during the past four years, compels me to express my decided opinion that the mechanical treatment of this affection is either useless or positively mischievous." He concludes that, having quite discredited the use of these mechanical contrivances, and contented himself with a recourse to cold vaginal injections, with the antiphlogistic treatment of any uterine inflammation, and the application of caustic to any ulceration of the uterus, and with the endeavour to remove the chlorotic symptoms which are seldom absent, he has been much better satisfied with the results of treatment than he was when he was seduced into the application of a variety of mechanical contrivances. (Lect., &c., p. 225.)

150. It is obvious from the foregoing, as well as from my own limited experience, that attention to the improvement of the general health, to the removal of the local lesions of the uterus with which displacement is often associated, as they admit of removal by local and constitutional treatment, to alleviation of the more painful or distressing symptoms, and to the improvement of the secretions and excretions, are the true principles which should guide the physician in the management of these complaints. The means which are chiefly required are such as have already been recommended, and the caustic employed may be either the sulphuric acid and sulphate of magnesia, or the superartrurite of potash, if the bowels be constipated; the sulphate of alum if this state do not exist, or the gallic acid, tannin, or the infusion of mattoe, may be prescribed internally, and conjoined with hebbon, or with conium, or with the extract or tincture of belladonna, or of the Indian hemp, if pain be urgent. After the second or third day, if the discharge be excessive, cold enemics may be administered twice daily; and in order to remove the amenorrhoea and debility generally characterising those cases, calomel and aperient preparations, if necessary, should be given, according to the circumstances of the case, should be given, and the diet and regimen strictly enforced.

151. VI. INVERSION OF THE UTERUS—the turning of the organ inside out—is clearly impossible in the unimpregnated healthy womb. It is one of the most disastrous accidents which can befall a female. My late friend Dr. Crosse of Norwich, in his elaborate essay on Inversion of the Uterus, states that, of 400 cases of inversion, of which he had found mention, 350 were consequences of parturition. Of the remaining 50 cases, 40 were said to have occurred from the presence of a polypus in the interior of the womb, the accident taking place either spontaneously or from traction in attempting to remove the growth. Enlargement of the uterine cavity, associated with some cause exciting contraction of its fibres, are the conditions essential to inversion of the organ.

152. A. The symptoms of inversion of the uterus are, sudden collapse or sinking, with abundant haemorrhage, with disappearance of the tumour formed by the uterus in the abdomen, and the presence of a large spherical body either just within the vagina, or projecting beyond the external parts. My friend Dr. Radford has, however, shown that, except in cases where the placenta still partially adheres to the uterus, the haemorrhage is not so formidable as might be anticipated; and that the shock to the system is in great degree independent of the loss of blood.

153. B. Inversion of the uterus is caused chiefly by the detachment of the placenta after delivery, owing to undue force or want of care; and, in rarer cases, by a spontaneous and unequal or irregular contraction of the uterus, either whilst throwing off the placenta, or even soon after or upon its detachment; whilst the cervix and os uteri are at the same time completely relaxed. This explanation of spontaneous inversion of the womb was ably given by Dr. Radford and confirmed by Dr. Simpson. The pressure of the bowels on the fundus caused by the action of the abdominal muscles during the detachment of the placenta may also favour this occurrence. A polypus or tumour firmly attached to the interior of the fundus uteri, having descended through the os uteri, may likewise excite irregular action and drag the fundus with it, thereby producing, with varying degrees of rapidity, inversion of the organ.

154. In most instances the inverted uterus becomes speedily firmly contracted; but in a few cases, the uterus remains soft and flaccid, and even capable of replacement. The haemorrhage often continues at short and uncertain intervals, and in very variable quantity from the period of the accident, but it is evident that there are occasional exceptions. The consequences of inverted uterus tend with varying degrees of rapidity to the destruction of life,—at least in the great majority of instances. Dr. Crosse states "that in 72 out of 109 fatal cases, death took place within a few hours, in 8 within a week, and in 6 more within four weeks. The immediate danger, however, being surmounted, there follows during lactation an interval of comparative safety and of cessation of serious symptoms, which reappear when suckling is over. It appears that of the remaining twenty-three patients only one died at the fifth month, and then, as the result of an operation which had an unsuccessful issue; one died at eight months, three at nine months, and the others at various periods of from one to twenty years."

155. C. The diagnosis of inversion may be overlooked and or mistaken. The inverted uterus has even been torn away by ignorant persons who had believed it to be the placenta. Dr. Crosse considered that the womb may be partially inverted spontaneously a short time after the detachment of the placenta, or depressed at its fundus. This may increase to involution; but the portion i
version, although attended by much vital depression and hemorrhage, will not occasion any tumour in the vagina, nor a complete disappearance of that formed by the uterus in the abdomen. Introversio of the uterus may, however, soon pass into complete involution. An inverted uterus may be mistaken for polyposis, and a fatal issue result, as indeed it has resulted, from this error. The history of the case generally will assist the diagnosis, but polyposis may complicate pregnancy, and may occasion both a tumour after delivery and hemorrhage. The firm contraction of the os uteri upon the cervix of an inverted womb causes the part to assume the form of a pedicle, thereby rendering the diagnosis more difficult, unless an examination be made per rectum, when the uterus, if inverted, will not be found in its place, whilst if the vaginal tumour be a polypus it will be found in its proper place, and probably also somewhat enlarged. The uterine sound, as improved by Dr. Simpson, will also aid the diagnosis, if properly used.

156. D. The treatment of inverted uterus is attended by great difficulty. If the accident occur before the detachment of the placenta, the removal of this body should be effected before the replacement of the uterus be attempted. Dr. Simpson’s accurate views as to the source of hemorrhage in parturition show that fears of serious bleeding in consequence of the removal of the placenta in these cases need not be entertained. Two modes of returning the uterus when inverted after labour have been recommended. The one by pushing back and indenting the inverted fundus with the finger; the other by grasping the womb between the fingers, compressing it, and by pushing it upwards into its proper situation. Either of these modes may succeed in recent cases occurring after delivery, whilst the organ is soft or falciform, or as long after as it may remain in this lax state. In these cases, as well as in others, in which the replacement is attempted either when the organ is more firmly contracted, or when some time has elapsed from the occurrence of the accident, chloroform may be found of use in facilitating the operation, although in some cases where this substance has been employed, no advantage was procured from it.

If the inverted womb cannot be replaced, immediately after the occurrence of the inversion, it will remain irreducible and entail on the patient all the miseries and perils incident to this state. The only means of avering these are by operations, which are attended by very serious hazards. The chief reasons which can be urged for such operations — the removal of the inverted organ by the knife or by ligature — are profuse hemorrhages or discharges endangering the patient’s life. Dr. West has given the following table of the results in 50 cases of inversion of the uterus after delivery, in which extirpation of the organ was performed.

157. It is of importance to know the results of extirpation at different periods from the time at which the inversion occurred. If the operation be performed soon after the occurrence of the accident it cannot be expected to be as successful as at a remote period from the occurrence, as the organ will diminish in size, vascularity, and sensibility by the lapse of time. Accordingly we find that, of 21 cases thus operated upon within twelve months from the occurrence of the accident, 9 died and 12 recovered, whilst of 25 cases in which the operation was not performed until one year or much longer periods had elapsed, 23 recovered, and only 2 died. Of the occurrence of inversion from a polyposis, and of the various modes and appliances for extirpating the uterus I must refer the reader to works on surgery, and to those enumerated in the bibliography and references to this article.

158. VII. Of Polypi of the Uterus.—Polypi and tumours of the womb generally occur during the period of sexual activity, or, if they be developed at a somewhat later period, or soon after the climacteric period, they have generally originated some time previous to it. It is often very difficult to ascertain the causes which either predispose to or excite their formation; but there is reason to infer that inordinate excitement or determination of blood to the uterus, with a disposition to hypertrophy of one or more of the tissues of the organ, are the chief causes of these lesions.

159. i. Mucous polypi or excrescences from the folds of the arbor vitae, are often met with, varying from a third of an inch to nearly an inch in length, to about three or four lines in thickness; they are connected with the mucous or villous membrane of the canal of the cervix, by a very slender and short pedicle. They are usually of a bright rose tint, are supplied with a delicate net-work of vessels, and consist of mucous membrane with a small admixture of cellular tissue internally. They may spring from any part of the cervical canal; but they more frequently arise nearer to the external than to the internal os uteri. Although generally pediculated, they are sometimes sessile, and in rare cases they seem as hypertrophied folds of the arbor vitae. These productions are either single or multiple, two or three existing in the same patient; and having been removed, they may be reproduced in a few months afterwards. They may even coexist with fibrous tumours of the uterus. Dr. Montgomery, of Dublin, believes them to be sometimes precursors of malignant disease; and this was observed in one case which was under my care. In rarer instances these polypi are much larger than now stated, and consist of a cellular or fibro-cellular tissue invested by mucous membrane; sometimes they reach the size of a fig, are flattened, and hang down beyond the os uteri into the vagina.

160. ii. Follicular polypi, or polypi from enlargement of the follicles of the cervix, are not infrequently observed. They appear as coats, of the size of a pea, imbedded between the folds of the arbor vitae, and hardly projecting beyond the level of the canal. They are, however, sometimes much larger, are more or less numerous, and are distended by albuminous matter. When
arge and numerous, they cause the absorption of the cervical structure, and even occasion the bulging outwards of the structure of the cervix.

161. iii. Complex polypi, consisting of mucous follicles, the mucous or villous surface, and fibro-cellular tissue of the cervical canal, are more frequently cured than the others of the foregoing. These polypi are either pediculated, the pedicles being sometimes of considerable length, more rarely very short, or appear as continuous tumours or growths from the inner surface of one or other of the lips of the os. When divided they are found to contain a tenacious, transparent, albuminous matter, identical with that secreted by the Nabothian glands. When small they consist chiefly of cysts filled with this matter. When they are much larger, and reach the size of the first joint of the thumb, these cysts or vesicles are not so distinct, but exist in the form of canals, arranged longitudinally, between which a fibro-cellular tissue enters more or less abundantly. Their surface often presents an uneven or tubulated appearance, is generally not very vascular, and is composed, according to Viancnon, of a dense cellular tissue, covered by a thick layer of tesselated epithelium.

162. iv. The symptoms indicating the existence of polypi generally appear gradually, and may with increasing severity continue months or even years before medical aid is required. There are usually at first leucorrhoeal discharge, haemorrhage, or both, followed by bearing down pains in most cases. When the polypi are very small, they may produce either very slight symptoms or no symptoms at all. Haemorrhage is, however, very generally experienced, especially when the polypi occasion enlargement of the neck of the womb. The size of the polypi may not influence the haemorrhage, a small one often causing more than a large one. Dr. West considers that the structure of the polypus influences the symptoms, and that those polypi which present the compound structure due to the enlargement of the Nabothian glands are always productive of profuse leucorrhoea; and that the profuse haemorrhage to which they are less frequently the occasion of haemorrhage.

The much rarer occurrence of follicular polypi, is attended by a profuse albuminous discharge, and is not associated with profuse menorrhagia, unless in rare instances. The symptoms now mentioned should always suggest digital examinations, and if no polypus can be felt, examination by the speculum becomes requisite.

163. v. The treatment of polypi is thus described by Dr. West. "The smallest may be removed by laying hold of them with a pair of long forceps and twisting them off, while those which are somewhat larger, after being twisted to check the risk of bleeding, may be cut off by a pair of scissors. The bi-valve speculum should always be employed in doing this, and both forceps and scissors are made for the purpose, so constructed as to be readily worked within the speculum." For the sessile growths or tumours, noticed above, (§ 159.), he applies the acid nitrate of mercury, which destroys them, and arrests the bleeding. As respects the removal of larger polypi and the several means of accomplishing it, I must refer the reader to the work just quoted, or to the surgical works where this operation is fully described.

164. VIII. Fibrous Polypi or Tumours within the Uterus are amongst the most serious organic diseases of the uterus, and the least amenable to treatment. They are uncertain in their rates of progress, being in some cases rapid, and in others slow; and in rarer instances almost altogether cured by the efforts of nature, which either throws off the morbid structure from the organ in which it is seated, or stops its growth. These tumours vary much in structure and in their seat. When they arise from the internal surface of the uterus, or underneath the internal membrane, they are generally considered as a form of polypus, and described as such, as fibrous polypus of the uterus. Dr. West considers them to be fibrous tumours, growing from the inner surface of the womb, or less frequently from either lip of the os uteri.

165. a. Fibrous polypus of the uterine is nearly identical with other fibrous tumours of the organ; and differ chiefly either in being developed immediately underneath the internal membrane, or in having more or less of the fibrous structure of the womb interwoven with or covering it. Fibrous polypus of the uterus is pediculated, and, growing from the interior of the womb, is more muscular than other tumours of the organ. The pedicle is composed of uterine fibres mingled with more or less dense cellular tissue. A layer of uterine substance is continued a short distance from the pedicle along the tumour, in some cases, or invests it in part, or altogether in others. In addition, the polypus is always covered by the internal membrane of the uterus, which becomes firmer and denser than natural, both it and the fibres of the womb being developed with the growth of the tumour. These tumours are generally single, but they are sometimes double, very rarely more numerous. They are of very different sizes, and occasionally remarkably large. They may, in some instances, be enucleated from their coverings; in others, their substance is intimately connected with their envelopes. The vascular supply of these tumours through their pedicles, is generally less, they are of smaller size and to the quantity of blood in their substance. This comparatively small supply of blood, the profuse haemorrhages they occasion, and the arrest of the haemorrhage by ligatures around their pedicles, have rendered it very difficult to determine the actual source of haemorrhage. Dr. West seems to believe that it is rather from the irritated mucous membrane of the uterus than from the surface of the tumour itself that the bleeding flows; and a variety of considerations confirm this opinion.

166. These polypi being generally formed within the uterus, influence the organ in some respects, according to the situation whence they spring. If they arise low down, or in the cervical canal, the tumour soon grows beyond these limits, and, passing down into the vagina, may acquire a considerable size, without disturbing the uterine functions. If they arise from some part high up, or near the fundus of the uterus, they often remain until they have acquired a great size, occasioning enlargement of the organ and thickening of its walls, as in pregnancy. But in many cases, before or soon after the tumour has reached the size of an orange, the os uteri gradually dilates, allows its passage through it, and embraces.
its pedicle. In some cases this result takes place without much suffering; but in others, violent uterine action is excited by the tumour, which recurs at intervals, and resembles the pains of labour. The tumour, or polypus, is thereby extruded from the introitus of the vagina, and the natural irregular contractions of the uterus, especially when the polypus is firmly attached near the funius, may drag down, or invert the organs, as stated above (§ 151.). Generally the polypus is detected soon after it has passed into the vagina; but if not detected, and when allowed to remain in this situation, it acquires a large size. I believe, however, that the largest tumours of this kind reach their full size within the uterus. In a case which came before me, and in which Dr. Lee was consulted, two tumours were thrown off of the size of between two and three pounds each, immediately after passing the os uteri.

167. Fibrous polypi may present edema of their substance, extravasation of blood into their structure; and having passed into the vagina they may undergo ulceration, especially if air come in contact with them, or even sloughing. When they undergo sloughing, they may refer to means which produce firm contractions of the uterus, as in two cases where this was effected by the treatment which I adopted, their pedicles give way, and the whole mass (fibrous structure and envelopes) is thrown off.

168. B. The Symptoms of fibrous polypi are nearly the same as mentioned above (§ 192.)—are leukorrhoea, hemorrage, and bearing down. The hemorrage is at first experienced chiefly at the menstrual periods which are prolonged, or return at shorter intervals, or are more abundant, approaching to flooding, leukorrhoea being present in the intervals, Bearing down is almost constant in some cases, or recurrent in others, with expulsive pains or efforts, when the tumour has far advanced. When these symptoms are present, a vaginal examination should not be delayed. If the polypi have not passed the os uteri, the diagnosis becomes very difficult. In these circumstances the diagnosis is not advisable by Professor Simpson, or dilatation of the os uteri by the sponge tent, as recommended by the same eminent authority, becomes necessary.

169. C. The Treatment of fibrous polypi has always hitherto been considered as entirely instrumental or surgical. In two cases which I treated, the means employed were strictly medical and proved in both, within a few hours, successful, the tumours having been extruded through the os uteri by the action of the uterus and entirely thrown off. In one of these cases the hemorrage was excessive. I prescribed immediately the bi-borate of soda in solution, and directed the dose, about six grains, to be repeated every hour or two. A tumour, about the size of a child’s head, was soon after thrown off; six or seven doses of the borax having been taken, when vomiting was occasional; but the hemorrage had very much improved and soon subsided before the tumour came away. A day or two afterwards hemorrage returned, a vaginal examination was made, the os uteri was found somewhat dilated, and another tumour was felt pressing upon the opening. I then requested Dr. Lee to see the patient with me, when he stated that the situation was unchanged, and the second tumour was expelled in a few hours by the contractions of the uterus. The only other case of fibrous polypus of the womb which I have had an opportunity of treating, was one of a single tumour of large size, much hemorrage had taken place, and I prescribed the rapid infusion of several grains of the bi-borate of soda as it would dissolve, to be given every hour or two, until eight ounces were taken. Soon after the whole was given the tumour was expelled.

170. The operations advised for removing fibrous polypi are by ligature and by incision. Dr. R. Lee records twenty-seven cases of the removal of fibrous polypi of the uterus, nine terminated fatally (West). Excision of the polypus has been dreaded in these cases, the risk of dangerous hemorrage from the operation having been considered great. Velpeau, Lisfranc, Dupuytren, West, and Arnott, however, greatly prefer excision to the ligature. Velpeau found the hemorrage troublesome only in two of twenty cases on which he thus operated. "Lisfranc states that he met with but two out of 165 cases; and Dupuytren also but two out of nearly 200 cases. What I refer to is the danger of phlebitis, or of peritoneal inflammation leading to a fatal issue after the operation by ligature." Torsion and strangulation of the pedicle by compression have likewise been advised for removing fibrous polypi; but they are liable to the same objections as have been urged against the use of the ligature. It is unnecessary to refer further to the mode of operating by excision, inasmuch as whoever is capable of undertaking the operation requires no directions respecting it, or, if he should, he will find them in Dr. West’s work now quoted, or in any systematic work on surgery.

171. I may here mention that fibrous polypi may co-exist with pregnancy, and thus, although remarkably small previously to impregnation, they may participate in the development of the uterus during this period. They do not, however, generally produce marked symptoms during pregnancy, nor interfere with its natural course. After the commencement of labour their injurious influence becomes manifest, either presenting a mechanical obstacle to the passage of the child, or giving rise to very serious consequences subsequently, by occasioning dangerous hemorrage, or other difficulties. They may also at this time lead to very serious mistakes as respects their diagnosis. The question as to their treatment at this time is of so small importance; for excision, however great the hemorrage, may be followed by phlebitis, or metritis, or pelvic peritonitis. Therefore, if the hemorrage cannot be controlled by opiates and astringents, the ergot, or the ovaria may be exhibited, at first singly, and, if they fail, afterwards in combination.

172. IX. TUMOURS IN THE WALLS AND EXTERNAL SURFACE OF THE UTERUS.—I. Description. a. These morbid growths are more or less intimately connected with the parieties of the womb, and are in many instances identified with the structure of the organ. Several tumours are more frequently formed in the same case, than one merely; but when this multiple, one or two generally outstrip the others in the rapidity of their development, the rate of which, as well as the nature of the symptoms, is greatly influenced by the situation given as before, and the second tumour was expelled in a few
uterine tumours are commonly firm, spherical in form, with nodulated surfaces, and their structure is sometimes interrupted by cavities containing fluid, and varies in density, elasticity, and succu- lency. They are thus well described by Dr. West: "On a section being made of any of these tumours, they are found to consist of a large greyish structure, intersected by numerous dead white bands and lines, which are almost invariably arranged according to a definite type or plan. In some instances these fibres have a concentric arrangement, while in others they have a wavy distribution, or are disposed around several different centres. Tumours of the first kind are usually remarkable for their hard- ness, and their small degree of vascularity; they are also contained within a remarkably distinct fibro-cellular investment, are imbedded in the uterine substance, and seldom attain a size exceeding that of a shielded walnut. The other varieties are more vascular, less firm, have a less complete capsule, may occupy all parts of the exterior or interior of the womb, and may grow to a very large size, so as to weigh twenty, forty, or even seventy pounds. Moreover, it happens sometimes, that in the course of their development, two or more tumours coalesce at least apparently, so as to form a large growth, though on a section it will be seen that the different growths remain distinct from each other, separated by fibro-cellular septa, the remains of the more complete investment by which, when smaller, each was surrounded." (West's Lectures, &c., p. 267.)

When these tumours are seated near to the internal surface of the uterus, or under the internal membrane, the fibres of the womb either passing over the surface of the tumour in some parts, or actually passing into it, they form the fibrous polypi, or internal tumours of the uterus already described (§ 104. et seq.). The vascularity of these tumours varies in different cases, and, like the tissues with which they are connected, they resolve into gelatine by boiling.

173. These growths may be developed in any part of the walls of the uterus. Sometimes they are formed in the part which lies lateral to the covering of the uterus, or in the middle of the ovarian ligament or Fallopian tubes, and are limited to the fundus, or upper part of the body of the uterus, more frequently on its posterior than on its anterior surface. They generally remain of a small size, and hardly exceed that of a pea or bean; seldom projecting further than one half of their bulk. In other cases they either grow outwards or inwards, from the thickness of the uterine parietes, being apparently only attached to them by a thick pedicle, into which some uterine fibres enter. The tumours which grow outwards from the uterine wall, sometimes attain the size of a large orange, or even a greater bulk; they, unlike the tumours which grow into the cavity of the womb, receive no investment of fibres from the substance of the organ, and are often present in considerable number. Dr. West remarks, as many of them being projecting from the external surface, the interior of the organ being free from disease. Wherever may be their origins, these growths tend as they increase in size, with few exceptions, to become pedunculated; these exceptions being the firm, slightly vascular tumour with concentric arrangement of fibres, which remains imbedded in the uterine walls, without projecting either externally or internally. In rare cases, also, the more vascular, elastic, and succulent fibrous tumour is developed in the uterine walls, attaining the size of the facial head, producing very great enlargement of the organ, and retaining a spherical shape, being imbedded in the substance of the womb, without projecting more in one direction than in another.

174. The influence exerted by these tumours on the womb depends more upon their situation than upon their bulk. When they are seated externally to the womb, and grow into the peritoneal cavity, they often acquire an enormous size, and the womb is much elongated, and even drawn upwards into the pelvis, but seldom increased in bulk. If, however, a small tumour be developed in the walls, or within the organ, more or less increase of size will be observed. These tumours reach the greatest size when they are single and attached to the external surface of the uterus. Walter has described one which weighed seventy-four pounds.

175. b. The ultimate changes which uterine tumours undergo, are interesting, and often tend, under the influence of vital resistance, to a more or less salutary issue. 1st. When the tumour is externally attached to the uterus, its pedicle may become ultimately so attenuated as to be detached nearly or altogether from the womb, especially if it had formed previously adhesions to the adjoining peritoneum; such cases are, however, very rare. 2d. When the tumour is developed internally, or passes into the cavity of the organ, it undergoes the changes and their results already described (§ 166. et seq.). 3d. The tumour is sometimes softened, the more liquid parts are absorbed, and either a calcareous substance is deposited, or remains after the other elements are removed; that the former or actual deposit of calcareous matter takes place is evinced by the quantity of the calcareous matter or deposit. This change takes place both in small and in large tumours, and most frequently in those attached to the outer surface of the uterus; but it may also, and more rarely, occur in those that are developed internally. Fibrous tumours of the womb were formerly believed to sometimes degenerate into cancer. This change is now considered never to occur. That a tumour, developed in the walls, or attached to either surface, of the uterus, may coexist with cancer of the cervix, is possible, and the coincidence has been observed in rare cases.

176. c. The frequency of tumours of the uterus has been very differently stated by writers; but they seem to be, with the probable exception of cancer, the most common of organic diseases of this organ. Mr. Pollock states that of 583 cases, in which the uterus was examined at St. George's Hospital, 265 were diseased, and in 39 of them fibrous tumours existed, and in 38 cancer was found. The statistics of the malady are very unsatisfactory. In 70 cases, in which Dr. West examined the uterus of women who died from the liberty of other than uterine diseases, 7 presented fibrous tumours of the organ. From these and other observations made by Malloigne, Braun, Chevallier, and others, tumours of the uterus are observed chiefly between the ages of twenty-four and sixty; and most frequently from thirty to sixty.
177. ii. The symptoms. — Tumours of the uterus are very often not manifested until they reach a large size; and they exist even many years without producing any inconvenience, or being suspected until they are detected after death. The growths from the inner surface of the womb frequently occasion no symptoms but those produced by them when they reach a great bulk; or when they disorder the sensibility or functions of adjoining parts. But those which are imbedded in the walls of the organ, disturb either the functions or the sympathetic relations of the womb, although their size may be small. It has been already shown that the growths or polypi which occupy the cavity of the uterus, occasion abundant haemorrhage and other phenomena. (§§ 162, 166.) When these tumours are formed after the cessation of the catamenia, the severity of the symptoms they occasion is much less than at an earlier epoch; and when they are developed in single women, the symptoms generally become much more severe after marriage, and they often either occasion sterility, or, if impregnation takes place, abortion. If pregnancy take place in these cases, the growths, though attended by much greater danger than in the healthy state of the uterus. The symptoms of uterine tumours are most commonly slight at their commencement, and slowly increase in severity. They sometimes, however, are sudden, more especially the uterine hemorraghages, which recur after intervals, and are more and more severe; but, unless caused by internal growths, are not followed by leucorrhoea or any offensive discharge. Dysuria, or retention of urine, sometimes suddenly occurs. As the tumour enlarges, pain in the region of the uterus, bearing down, and sense of discomfort in the pelvis, are felt, with frequent calls to pass urine. The character of the pain is somewhat peculiar; it is rather a dull, aching, or gnawing, but constant pain, seldom preventing sexual intercourse; yet sometimes attended by throbbings, or a sense of hotness or burning, or after urination. The tumours are nodulated, or uneven, nodulated, solid, are attended by alteration of the lower segment of the uterus, and by the absence of, or difficulty of finding, the cervix and os uteri, and not infrequently by retention of urine.

180. The haemorrhage attending tumours of the uterus, may be mistaken for abortion. The patient not infrequently encourages the opinion of pregnancy from a desire of being in this state, and care should be had not to be thus misled; but to question the patient as to the history of the case; and to examine locally with care and with reference to contingent disease of the uterus and of its appendages. The frequent recurrence of haemorrhage; the absence or character of pain, and the state of the cervix and os uteri will generally guide the diagnosis in these cases.

181. Fibrous tumour of the posterior uterine wall may be cause of neuralgic pains such as have been already described. (§ 7, et seq.) When these symptoms are present, the abdomen, especially towards the pelvis, should be carefully examined; and if any tumour be detected, the diagnosis between an uterine and ovarian tumour should be made.

178. iii. This diagnosis is extremely difficult, and cannot be attempted without a careful examination first of the abdomen, and next per vaginam and in both situations. Tumour of the uterus, when so large as to be felt on examining the abdomen, is always firm, frequently nodulated or uneven, seldom mamil, and generally inclining to either side. On examining per vaginam, the tumour, if uterine, rarely draws the uterus upwards, unless it be attached near the fundus. It is most frequently seated in the posterior parietes, and is, more especially in these cases, accessible to examination. It is then found to be firm, sometimes uneven, carrying the cervix towards the symphysis pubis, and often more or less retroverting the organ, and often displacing it somewhat from the mesial line. The os uteri is generally small, circular, and healthy; or somewhat hard, or enlarged, or turbid. If the tumour be intra-uterine, or in the walls, it is found larger, heavier, and less movable than natural, and if it be seated low in the womb, the cervix uteri will not be unlike the form assumed in pregnancy, not unfrequently disappearing, and its lips being thinned. Dr. West remarks, that an enlarged, heavy, and somewhat hard uterus, coupled with rise of the woman and frequent return of uterine hemorrhage, while the os and cervix uteri are healthy, and I might add absence of pain, or but slight pain during coition, are almost always pathognomonic of fibrous deposit in the uterine substance.

179. Tumour of the uterus must be large to be mistaken for tumour of the ovarium. The former is always slowly developed, and rarely rises out of the pelvic cavity; the latter much more rapidly increases in bulk, and when large rises out of the pelvis. The one is hard, and non-fluctuating; the other is softer, and more obviously, if not more manifestly, fluctuating. The ovarian tumour generally attains a much greater bulk than the uterine, is at first more inclined to either side, and is seldom attended by haemorrhage during its growth; or by retention of urine when largely developed. The cervix uteri is sometimes drawn upwards, but is seldom altered as abortions, and are attended by much greater danger than in the healthy state of the uterus. The symptoms of uterine tumours are most commonly slight at their commencement, and slowly increase in severity. They sometimes, however, are sudden, more especially the uterine hemorraghages, which recur after intervals, and are more and more severe; but, unless caused by internal growths, are not followed by leucorrhoea or any offensive discharge. Dysuria, or retention of urine, sometimes suddenly occurs. As the tumour enlarges, pain in the region of the uterus, bearing down, and sense of discomfort in the pelvis, are felt, with frequent calls to pass urine. The character of the pain is somewhat peculiar; it is rather a dull, aching, or gnawing, but constant pain, seldom preventing sexual intercourse; yet sometimes attended by throbbings, or a sense of hotness or burning, or after urination. The tumours are nodulated, or uneven, nodulated, solid, are attended by alteration of the lower segment of the uterus, and by the absence of, or difficulty of finding, the cervix and os uteri, and not infrequently by retention of urine.

180. The haemorrhage attending tumours of the uterus, may be mistaken for abortion. The patient not infrequently encourages the opinion of pregnancy from a desire of being in this state, and care should be had not to be thus misled; but to question the patient as to the history of the case; and to examine locally with care and with reference to contingent disease of the uterus and of its appendages. The frequent recurrence of haemorrhage; the absence or character of pain, and the state of the cervix and os uteri will generally guide the diagnosis in these cases.

181. Fibrous tumour of the posterior uterine wall may be cause of neuralgic pains such as have been already described. (§ 7, et seq.) When these symptoms are present, the abdomen, especially towards the pelvis, should be carefully examined; and if any tumour be detected, the diagnosis between an uterine and ovarian tumour should be made.

178. iii. This diagnosis is extremely difficult, and cannot be attempted without a careful examination first of the abdomen, and next per vaginam and in both situations. Tumour of the uterus, when so large as to be felt on examining the abdomen, is always firm, frequently nodulated or uneven, seldom mamil, and generally inclining to either side. On examining per vaginam, the tumour, if uterine, rarely draws the uterus upwards, unless it be attached near the fundus. It is most frequently seated in the posterior parietes, and is, more especially in these cases, accessible to examination. It is then found to be firm, sometimes uneven, carrying the cervix towards the symphysis pubis, and often more or less retroverting the organ, and often displacing it somewhat from the mesial line. The os uteri is generally small, circular, and healthy; or somewhat hard, or enlarged, or turbid. If the tumour be intra-uterine, or in the walls, it is found larger, heavier, and less movable than
for several, if not for many years, unless they are very large, or are productive of very serious symptoms, or are associated with pregnancy. In this latter state the abortion they generally occasion, or purgation at a natural period, is often attended by more or less danger. When the tumour is intra-uterine, constituting the fibrous polypus above described (§ 164, et seq.), a cure is then generally accepted. But the anti-tumorative and anti-parasitic or tuberculiferous remedies, the infusion or tincture of manna, the spirits of turpentine, the extract of log-wood, &c., may be had recourse to. When the tumour is amnestic, or when there is a more continued draining of blood, the triturated tincture of iron, with an additional quantity of the acid, will be given with benefit, with the compound tincture of camphor, or with the infusions of columb or quassia.

186. I have had reason to believe that a judicious recourse to the iodides has not infrequently been productive of some benefit. The iodide of potassium should generally be preferred, and be conjoined with the solution of potassa, or with Brandy's alkaline solution, or with either of the carbonates; but it ought always to be prescribed in small doses, and be long persisted in. In other, or in anemic, cases, the iodide of iron may be given in syrup of sarsa. The bromides of magnesium and of potassium have been considered as being equal, if not superior, to the iodides, chiefly from the circumstance of their presence in certain mineral springs, as those of Kreuzbach, which have been much employed, both internally and as baths and hipe-baths daily, in cases of uterine enlargements and tumours, and with apparent benefit in many cases. These waters may be had in this country. M. Velpeau suggested an operation consisting of the excision of fibrous tumours of the uterine parietes by an incision through the os uteri or the lower segment of the womb. M. Amurath performed this operation in 1840, and it has been subsequently resorted to by others—by Bérard, Boyen, Simpson, and others; and with success by my friend Dr. Pancoast of Philadelphia, by Mr. Treadle of Leeds, M. Amurath, in two cases, and by M. Maissir, in another; but as the tumours are more frequent than is supposed, and as the disease is much greater than that of the successful; and as their details are by no means encouraging, the hamorrhage and other consequences being alarming, this operation should not be recommended.

187. X. TUBERCULAR DEGENERATION OF THE INTERNAL SURFACE OF THE UTERUS is sometimes met with, in the form of a dirty yellow matter, closely resembling the substance of a tubercular bronchial gland at an early stage of softening. This matter is about an eighth of an inch in thickness, extends over the whole internal surface, but rarely into the cavity of the cervix, and more frequently into the Fallopian tubes, which it more or less distends, and is sometimes associated with tubercular degeneration of the ovaries. I observed this association in a young lady who died of consumption at nineteen years of age, and who had never menstruated. Resortant thinks that it never occurs primarily, and that it takes place from the scraping off this deposit from the internal uterine surface, it is found that the whole of the internal membrane is removed and replaced by it, and that it is closely applied to the proper surface of the organ, which, with its cavity, is more or less.
UTERUS.—CANCER OF THE. — FORMS OF.

enlarged. At an earlier stage the internal membrane is seen to be opaque, more vascular than natural, and to present small yellow spots, which are found to be distinct tubercular deposits when examined by the microscope. This subject has been investigated by Louis, Kruse, and Gerl, the last of whom, Dr. West, with an admirable accuracy, according to which it appears, that, in 68 cases this lesion has been observed at all ages, from 10 years to 80; but most frequently from 20 to 50 years of age; and, according to the appearances in 45 cases, the uterus alone was affected only in 1 case; the uterine and tubes in 12; the uterine, tubes, and peritoneum in 15 cases; and the tubes alone in 8 cases.

188. The symptoms of uterine tuberculosis are amenorrhoea, or dysmenorrhoea, often associated with leucorrhoea,—very common phenomena of tuberculous placitis, of which this uterine lesion is generally secondary, or, if not secondary in very young subjects, at least co-existent with tubercular deposits in the lungs and other organs or parts.

189. XI. Fatty formations have been deposited in the cavity of the uterus in very rare instances, and have been mistaken by the contractions of the organ when they had reached a large size. Dr. West refers to two instances, recorded by Drs. Busch and Sehler, where this product was expelled from females of the ages of fifty and fifty-three. In one the tumour was the size of the fist, and was composed of fatty matter closely resembling cholesterol. In the other case the tumour was the size of a child’s head, was connected by a broad pedicle with the whole margin of the os uteri. It was removed by ligature; and the patient who had suffered from amenorrhagia for a year previously recovered. The tumour weighed three pounds and a half, was said to have been an ordinary fatty tumour, having an investment of dense cellular tissue, septs of which dipped into its substance.

190. XII. CANCER OF THE WOMB.—Of CANCER and of Scirrhous and other Tumours, as well as Fungo-Hematomata, and of other malignant diseases, full descriptions will be given under their respective heads. I shall now only briefly notice the malignant lesions which are found in the uterus, and the treatment which has been advised for them. Before the chronic inflammatory states of the cervix uteri were investigated and their consequences shown, more especially by the writings of Dr. Henry Bennett, several of these consequences were viewed as incipient cancer of this part of the organ; and the mistake was more readily made as cancer uteri in most cases commences in this part and often resembles the changes, more especially hyper trophy, hardening, pains, &c., which result from protracted inflammatory irritation. The profession is much indebted to the writings of Dr. H. Bennett, and more recently of Dr. West, for the researches they contain into the diagnosis of malignant diseases of the womb by the former, and into the pathology and treatment of them by the latter; and I would advise the reader not to be content with the brief view I shall now take of these maladies, but to peruse the more copious details, furnished by these able writers, not only of these but also of other diseases of the uterus.

191. I have defined CANCER, when treating of this malady generically; but much confusion has existed in consequence of the want of precision in the use of this term; for some pathologists have employed it as representing the genus of malignant alterations of structure, commencing or manifesting themselves locally; whilst others have limited it to Dr. West; and a variety of the genus. The generic definition of Cancer given by Müller, is as follows:—“Those growths may be termed Carcinomata, which destroy the natural structure of all tissues, which are constitutional from the very commencement, or become so in the natural process of their development, and which, when once they have infected the constitution, if extripated, invariably return, and conduct the person who is affected by them to inevitable destruction.” To this definition no objection can be offered, inasmuch as it comprises all the varieties of morbid structure usually denominated malignant or carcinomatous. Much confusion, however, has arisen from the different terms by which these have severally been denominated, the desire of originating a name, rather than of conveying a precise idea of the thing named, and of adopting foreign terms, being better calculated to suit the taste of writers than the usefulness. Cancerous diseases of the uterus, notwithstanding the microscopic researches of those anatomists who have dignified themselves by the name of Histologists, have not as yet been distinguished by any determinate character, by which they can be undoubtedly known under the microscope, as far as the describers of these characters or appearances have furnished us with the means; and this failure of microscopic diagnosis is most remarkably manifest in respect of those lesions of structure which have been viewed as carcinomatous by some, and which have been as stoutly denied to be such by others, and which are considered by the latter as separate and specific forms of disease, espically epithelial cancer, melanosis, lupus, &c.

192. i. FORMS.—Although no form of Cancer is peculiar to the uterus, yet they do not all occur with anything approaching to the same frequency. On this subject Dr. Bennett states that medullary carcinous is by far the most common; next in frequency may be classified the epithelial varieties of the disease, if indeed it be not more correct, as some men of high authority believe, to refer them to a separate category distinct from genuine cancer. Next to them, but divided by an interval which widens in exact proportion as fresh evidence is brought to bear on the subject, may be classed scirrhus or hard cancer; while almost as rare, or, perhaps even more uncommon, stands the colloid or alveolar variety of the disease.” (Op. cit. p. 330). Rockitansky says also that fibrous or scirrhus cancer of the uterus is of extreme rarity, whilst medullary carcinomata occurs with the greatest frequency. This opinion accords with those of Mr. Paget and Dr. West. But Professor KRESCHI states that scirrhus or hard cancer occurs in about three in every ten cases of cancer of the womb. I would advise the reader not to be content with the brief view I shall now take of these maladies, but to peruse the more copious details, furnished by these able writers, not only of these but also of other diseases of the uterus.
in medullary cancer. Dr. West states, that of 120 cases of uterine cancer, the disease appeared, from an examination during life, to be medullary in 108, epithelial in ten, and colloid in two; and of 120 cases, the disease occupied the body of the uterus only in two.

193. It is fairly shown that the cervix, or the part of the womb which projects into the vagina, is that in which cancerous disease commences, and that the exceptions to this are very few. The mode of its commencement, however, varies in the different forms. The medullary form begins with a morbid deposit in the substance of the cervix, enlarging or thickening it more than elongating. The lips of the os are enlarged, hard, and tense, and, at the same time, irregular, nodulated, and wide or gaping. When the cervix is incised, the structure is occupied by a white, firm, and semi-transparent matter, which seems infiltrated in parts, and has displaced the structure in others. This deposit is more abundant near the internal or mucous surface than near the external. Softening of the diseased part soon takes place, death of the mucous covering follows, and an ulcer, with ragged and uneven surface, and with raised, irregular, hard edges supervenes, and is covered by a dirty sanguineous discharge. As the disease proceeds, the lips and cervix are altogether destroyed, and the eroded parts are covered by a soft, dirty white, and often offensive substance.

The carcinomatous ulceration may commence, either in the softening of the morbid deposit, extending externally or superficially, or in erosion of the surface, the consequent ulceration proceeding more deeply; but the formation of the open sore takes place sooner or later, and advances with very different degrees of celerity; foul granulations and fungous growths spring forth; a foul pur, mixed with a feclid, greenish-brown, or sanguineous fluid, or bloody débris, or with more or less abundant haemorrhages, marking the progress and destruction of the lower segment and upper portion of the vagina. In the more retarded cases, cancerous deposits take place in the substance, in the cavity, or on the external surface of the organ in the close vicinity of the cervix; and ultimately the disease invades more or less the whole body of the uterus, often extending to the ligaments and ovaries, and sometimes forming malignant polypi within the cavity. Cancerous tumours also form on the uterine peritoneum surface.

194. A. The scirrhous variety of cancer uterus is described by Rokitansky, as very rarely affecting the uterus; the most common form being the medullary, either by itself or complicated with the former. Fibrous or scirrhous cancer always commences in the cervix, its primary occurrence in the body of the uterus being extremely rare. When closely examined, it appears to consist of dense, whitish, reiform fibres, differing from the healthy tissue, and in their minute meshes a pale reddish yellow, or greyish translucent substance is deposited. This morbid growth invades the uterine structures, the cervical and vaginal cavities. It is various in extent, and accumulating at certain points, gives rise to irregular, nodulated elevations and indentations, and enlargement of the cervix, or porum vaginalis uteri.

195. Cancerous degeneration of the uterus in either of these forms is generally confined for a considerable time to the vaginal portion; but the disorganization often extends with more or less activity not only to the body and fundus of the organ, but also downwards involving the vagina, thus associating with it vaginal cancer. It may even extend in other directions and thus invade the rectum, the bladder, the cellular and adipose tissues of the pelvis, and at last the ovaries and the peritoneum, cancerous growths either forming upon it, or perforating it chiefly in the state of medullary masses. The destructive process, when extending to the vagina, predominates on either the anterior or on the posterior wall; sometimes to both equally, and occasionally almost to the external orifice. In these cases it often involves the parietes of the bladder and rectum, producing in the most advanced states communications between their cavities, and the most distressing conditions, consisting of a large fungoid cavity, occupying the vagina, the uterine cavity, opening into the cavities of the bladder and rectum, and closed superiorly by the parts agglomerated around the fundus, by the medium of adhesions between the peritoneum covering the adjoining viscera. The formation of these adhesions increases the distressing symptoms of the last stage of the malady, dirty sauries.

196. Cancer of the uterus is generally a primary malady, and continues for a long time, if not throughout, the only cancerous affection of the body. It is, however, sometimes developed concurrently with, or consequent upon mammary or ovarian cancer; or it may be accompanied with or followed by degeneration of the structures just mentioned and of the lymphatic glands. It more rarely becomes associated with cancer of the stomach, or liver; more frequently with that of the mammary and peritoneum, and occasionally with an universal cancerous deposit, or with multiple osseous. Uterine cancer seldom terminates fatally without extending to the upper portion of the vagina. It is commonly allowed that cancer uterus is confined to the part it commences in for a considerable period, and for a longer time than cancer of any other organ. M. Lebert states that secondary decapitancy, of the prostate, occurred only in a third of forty-five cases of uterine cancer. Professor Kiwich found the disease present in the bladder in 42 per cent. of his cases of uterine cancer. But in this, as well as in other diseases, statistics cannot be depended upon, and for reasons I have stated in other places.

197. C. Epithelial cancer, or Cauliflower exccrescence of the os uteri, and which is doubted by some to be cancerous, is of very rare occurrence. It presents a cauliflower appearance, or, according to Rokitansky, the appearance of a coniferous growth, consisting of lenticular, pale-red, transparent, and tolerably soft bodies, strung together like the beads of a rosary, projecting on the orifice of the uterus into the vagina, and bleeding on the slightest touch. The only case in which I have seen it, came only once before me in consultation, and it then seemed to me as a fungoid form of cancer; and, from the local changes, the bleeding upon examination, and the cachetic and nervous appearance of the patient, as undoubtedly a variety of carcinoma or cancer. The case observed by Rokitansky is stated by him to have grown from an evidently cancerous base of the medullary variety. Dr. J. Clarke and Mr. C. N. A.
Clarke, who first described this malady, have viewed it as less formidable, and have stated that that it is sometimes curable. It is not improbable that the medullary form of cancer of the cervix may present fungoid or conoid growths, of a cauliflower appearance; and that an intractable but non-cancerous ulcer of the os uteri may give rise to large fungoid granulations bleeding on the slightest touch, and both lesions may be thus confounded, the former, however, not admitting of cure, the latter in rare cases. Both these lesions are attended by frequent, exhausting, and dangerous hemorrhages. These morbid growths consist, microscopically, of " hypertrophied papillae, composed of epithelial cells, richly supplied in their interior with large and delicate vessels, and covered by a thickened layer of epithelium. The enormous looped capillaries of the cauliflower excrescence explain the abundant hemorrhages, and the profuse serous discharge which attend it; while the absence of that solid structure which is found in other forms of epithelial cancer accounts for the favourable results that have followed its extirpation."

198. D. Corroding ulcer of the os and cervix uteri, as described by Dr. J. Clarke, begins in the mucous membrane, and involves the whole circumference of the os, utterly destroying both it and the subjacent parts. It differs from cancer in the absence of thickening, hardness, or deposit of heterogenous matter, and in its prolonged existence — sometimes for several years without being attended by any dangerous symptoms. It appears to be analogous to lupus, and is more strictly a rodent form of ulcer, than a variety of cancer.

199. ii. Symptoms of Cancer Uteri. — The symptoms which are most constantly observed in cancer uteri — namely, pain, hemorrhage, and vaginal discharge — may attend other lesions of the organ; but in all cases where they, or even any two of them, are present, a careful vaginal examination ought to be made. — a. Pain, accompanied with hemorrhage or leucorrhrea, is a very frequent but not a constant symptom. It varies much in character and intensity, both at the commencement and in the course of the malady; and very often, when the hemorrhage is profuse, but little pain, or merely a backache, is felt. At an early stage the pain is generally not severe, nor is it always referred to the uterus, but more commonly to the loins. The organ is seldom tender to the touch, and sexual intercourse is not often productive of suffering. The pain, as the disease advances, is referred to one or other of the iliac regions, and either comes on, or is exacerbated in paroxysms, and a lancinating pain referred to the uterus occurs suddenly and at intervals. Menorrhagia may be either attended, or not attended, by pain. In many cases it is, when very profuse, followed by severe pain. With the progress of the malady the pain generally becomes more severe; but towards the close, when the cachexia and anemia are most remarkable, the sufferings of the patient generally abate more or less. But before this ultimate stage appears, pain in the uterus is added to that in the back and hypogastrum, and to the other distressing symptoms experienced. The pain is, in some cases, described as burning, darting, cutting, &c.; and it is generally aggravated into intolerable paroxysms, especially towards or during the night, stabiloring or lancinating pains recurring after short but irregular intervals. When an attack of hemorrhage supervenes on severe pain, some degree of relief is sometimes afforded for a short period. As the disorganisation extends to the bladder, the vagina, or rectum, or even to them all more or less, the sufferings of the patient are accordingly increased; and when utero-vesical fistula is formed, the distress is further aggravated, and rendered still more harassing. In a very few cases, however, the disease runs its course entirely, or almost entirely, without pain. But it is not so rare for pain to be absent through a great part of the course of the malady, and appear only at a far advanced period. The absence of pain throughout the disease, or until an advanced stage, occurs chiefly in the epithelial and medullary forms of cancer uteri.

200. i. Hemorrhage is the next symptom in importance; but it is not always a sign of the commencement of the ulcerative stage of cancer uteri, for it is, in a very large proportion of the cases, the earliest sign, preceding, and unattended by, either pain or watery offensive leucorrhoea, for a longer or shorter time. The occurrence of hemor-

201. i. The leucorrhoeal discharges differ in the forms and stages of cancer uteri. A mucous or muco-puriform discharge is frequent at an early period, and is then generally not offensive. But as the malady advances, it is commonly more or less offensive, and it becomes more watery, or appears as a dirty and very offensive sanies. An offensive discharge may accompany any of the chief organic lesions of the uterus; but, although it may exist in these, it seldom occurs in so marked a manner as in cancer. The continuance, the quantity, offensiveness, and other conditions of the discharge, depend upon a variety of circumstances — upon the
stage and form of the malady, upon the extent to which ulceration has advanced, upon the retention or non-retention of the morbid fluid, upon the frequency of its removal by injections, hemorrhages, &c. In a few instances, an offensive discharge has preceded either the pain, or the hemorrhage, or both, although much more rarely; and, still more rarely, this has existed for so long a period, and has given rise to so little suffering of cancerous nature, that it is impossible to say when the last recourse to medical aid has been had, the cervix uteri has been destroyed, and the finger has passed into the cavity of the organ.

202. These symptoms, the most severe which attend cancer uteri—the pain, the hemorrhage, and the offensive leucorrhce—a cannot undoubtedly prove the existence of the malady. They may individually, or even conjointly, attend other organic lesions of the uterus. But viewing them severally and in connection with the evidence furnished by a vaginal examination, and with the constitutional symptoms characterising the course and the advanced state of the malady, I set (see art. Cancers, §§ 20, et seq.), especially the cancerous cachexia, the existence of cancer uteri cannot be mistaken. The remarkable disorder of the digestive organs, the impaired assimilation, and the waste of the red globules of the blood, and even also of the tissues, and the consequent cachectic or cancerous anemia; the frequent recurrence of disorder of the bowels, more especially of diarrhceae, with both abdominal and hypogastric pains; the distress often caused by defaecation, and more particularly by the state of the urinary organs, and by the urinary discharges, are all indicative of the nature of the malady.

203. Cancer uteri does not prevent a female from becoming pregnant at an early stage of the malady; but it is of course of no importance. The changes in the uterine organs and in the female economy that follow, generally accelerate, often with great rapidity, its course. Parturition, owing to the effect of this act upon the diseased parts, especially the cervix, often is accompanied by dangerous hemorrhage, or followed by severe or fatal inflammation. In some of these cases, both mother and child have died before delivery has been accomplished; generally the process is difficult and prolonged. In some cases, gestation is also prolonged beyond the natural period, and, in rare instances, death has occurred without the efforts of the uterus having being sufficient to expel the fetus.

204. Dr. West has given, in his interesting lectures, a table of the result of seventy-four cases of cancer of the cervix uteri complicating labour; and of these 41 died soon after labour, and 33 recovered for a time from the effects of this process. Of 72 children, it is stated that 47 were dead-born, and 25 born alive. He found that the average duration of 17 cases of cancer uteri, which he carefully observed, was 16 months; and that of 29 cases, as given by Lister, was 16 months. It is thus apparent that cancer uteri is more rapid in its progress than cancer in other organs. The average duration of all forms of cancer is stated by this writer to be 18 months, and of cancer of the mamma and of the testis, the most prolonged, not to exceed three years and a half.

205. iii. The Prognosis of cancer uteri may be inferred from what I have stated above, and in the article Cancer (§§ 20—22.) Rokitansky remarks that "cases of cancerous origin in the uterus are of extreme rarity, but they do occur; the carcinoma and the cancerous ulceration are then limited to the cervix, the internal orifice forming the boundary. The loss of substance heals with a funnel-shaped cicatrix." (Op. cit. p. 308.) In a case, the progress of which was constantly observed by me, the recovery took place whilst a diet and regimen, hereafter to be noticed, was strictly observed. The cicatrix, which was formed low in the vagina, was shaped as Rokitansky has described it; not more than half an inch of the vagina above the urethra having been left uncontracted.

206. iv. Causes of Cancer Uteri. These are the same as have been stated respecting cancer in general. But there are certain particulars which require notice with reference to this malady, when originating, as it commonly does, in the neck of the womb. The mortality of cancer in females is the nearly three times greater in the latter than in males, and more than double the number of the deaths from cancer in males throughout England; the excess in females being evidently due to the frequency of cancer of the womb and of the breasts among them. According to Tanet, the deaths from cancer of the womb, stated in the Mortuary Registers of Paris, even in years in which those from cancer of the breast, were as 2½ of the former to 1 of the latter.

207. Age manifests predisposes to cancer; but this disease appears to occur at an earlier period in the uterus, than in the mamma; for in the latter it is rare at the age of thirty, whereas it is not so rare at this age in the former situation. Cancer uteri increases in frequency with the advance in life, as Dr. Walsh has shown; but in order to render the increase more manifest, the number of cases at a given age should be calculated with reference to the number of females supposed to exist at the same age and period. This is not the case in the register of life. The inference deducible from this fact is, that the occurrence of cancer is in some degree favoured by the depression or exhaustion of vital forces.
power taking place from the progress of age; as well as from other causes of vital depression. Dr. West has given a table of the ages of 426 cases of cancer uteri, collected from various sources:—

<table>
<thead>
<tr>
<th>Actual</th>
<th>In the proportion of 1 to 10,000 of the whole population existing at the respective ages.</th>
</tr>
</thead>
<tbody>
<tr>

</table>

From this data it would appear that, although cancer uteri becomes more frequent as life advances up to fifty or sixty, it diminishes considerably in frequency from these ages; and from this table, as well as from other sources of information, it cannot be inferred, that the actual cessation of the catamenia has any influence in favouring the occurrence of this malady in the uterus. Dr. West justly remarks that the state of the uterine functions previously to the appearance of cancer is not without interest; and he adds, that in 108 cases, this matter was made the subject of special inquiry. In 94 cases these functions were in all respects natural from their complete establishment to the commencement of the disease; and in 14 they were either habitually or frequently unnatural, being painful, postponing, or irregular. Out of 116 married women affected with cancer uteri, only 7 were sterile. The hereditary predisposition to cancer has been well established, as shown in the article on Cancer (§ 23). Mr. Paget found that this malady in all situations was hereditary in the proportion of one to 6:1; Mr. Leber, in the ratio of one to 7:2; and Dr. West in 1 to 6:2. The proportion of hereditary cases is very probably higher than here stated, as it is difficult to ascertain from the patients the nature of the disease which caused the death of either, or of both parents.

208. v. Treatment of Cancer Uteri is necessarily confined to palliating the suffering of the patient, and to attempts at delaying the approach of death. The symptoms which more especially require mitigation are hemorrhage, pain, and the offensive discharge. The means which should be resorted to for the first and second of these have been fully described in the articles Hemorrhage, Neuralgia, and Cancer; but there are a few topics connected with the treatment of cancer afflicting the uterus, and of the effects of this malady, which require further consideration.

209. a. Hemorrhage is amongst the earliest and most alarming symptoms of cancer uteri. The obvious intention is to abate it when severe or too frequent, and to prevent its recurrence altogether, or before the catamenial period. The various means usually employed for Hemorrhage from the uterus have been detailed (see art. Hemorrhage, §§ 263—273.); but there are a few of these which require a more particular notice at this place.

The gallie acid in doses of six to eight grains of every four or five hours, have been often found of decided service in arresting the hemorrhage. The infusion of mactis, used as an injection into the vagina, is also very efficacious. Dr. West states that, in some cases of medullary and of epithelial cancer, when the hemorrhage is excessive, or prolonged, the merthiolate issue may be broken down with the finger, and the tincture of the securiala-rude of iron injected into the midst of it. The extravasated blood is thereby coagulated, and the vessels destroyed, the whole mass thus treated sloughing away. Kiewisc, who first resorted to this practice, remarks that it is not attended by much pain or serious constitutional disturbances. He also advises a recourse to the actual cauterity, where the surface is too firm to be broken down. In one case, after other means had failed, I recommended the injection of the spirits of turpentine, in the manner in which the tincture of the mutiate of iron has just been advised, the same medicine being given frequently by the mouth in small doses; and the hemorrhage was for the time arrested. It is obvious that sexual intercourse is liable to occasion an attack of hemorrhage; and that it should, therefore, be strictly forbidden whenever cancer uteri is suspected.

210. b. Pain is often so excessive as to require energetic means of relief; but, as long as it is not acute, the gentler remedies only should be employed. The pain is sometimes brought on, or aggravated by an irritable state of the bladder, or by the condition of the urine, and not infrequently by neglect of the functions of the bowels. Therefore, the states of both the urinary and fecal evacuations should receive due attention. The former may be corrected, and the irritable condition of the bladder mitigated, by the exhibition of the solution or the bi-carbonate of potash with tincture of henbane, or by the mineral waters of Ems or of Vichy. If the urine abounds in the phosphates, the means I have advised for this condition, when treating of the morbid states of the Urine (§§ 90. et seq.), especially the hydrochloric acid taken in the decoction of pareira, or in the infusion of buchu, may be prescribed. The bowels may be regulated by means of the gentle cooling aperients ordered above (§ 184.).

211. When the pain becomes so severe as to require astringents, then plasters of opium or bella-donna may be applied over the sacrum or above the pubes; and chloroform may be tried as an epithem, by means of spongeo-paltine. Internally, the pilulae coconum cum opio, or tincture of opium, may be given at night; and if these occasions neither headache nor sickness in the morning, they may be continued without increasing the dose. The preparations of morphia, unless conjugated with aromatic stimulants, often cause unpleasant depression. The black drop, and Batty’s sedative solution, are often preferred to other opiates, but they are efficacious chiefly in their more powerful narcotic effects, the subsequent distressing sickness, &c. being not less complained of. Henbane and conium are often employed. The former, without alleviating pain, or with slight alleviation only, often produces restless sleep, leading to insensibility and headache. I have, however, found the two conjoined with camphor—three grains each of camphor, and of the extracts of
hemp and cinemon, being more or less of service.

Dr. Warr says that after hemp can be generally made a trial of the Indian hemp; for, although it is an uncertain remedy, it does not disorder the stomach, or occasion headache. But I have not always found it so pleasant in its ultimate effects. In severe paroxysms of pain, the inspiration of the vapour of chloroform has been resorted to; but the relief has been only very temporary. I have, in a few cases, directed the application of the tincture of belladonna to the diseased part, in the manner advised and resorted to by the late Dr. Moore (§ 15.) with very marked relief. Taken internally, belladonna seldom affords much relief, unless in large doses, which are usually followed by much depression, unless they are conjoined with aromatic stimulants; and these latter often fail in correcting the evil.

212. c. The discharges, owing to their great excess, or their very offensive odour, require, besides the usual attention to cleanliness, the means which have been advised for the more severe cases of Lecorrhoas. More especially the infusion of matico, or tanin; the decoctions of oak-bark, of buchu, of cedar-bark, or of pomegranate bark, &c. Weak acid lotions, and various other astringents, have also been recommended. Dr. Warr mentions the use of an injection of $\frac{3}{4}$ of a grain of sulphate of iron, and $\frac{3}{4}$ of a pint of water; and he adds that a solution of $\frac{3}{2}$ to $\frac{5}{8}$ of nitrate of silver to an $\frac{3}{4}$ of water injected immediately into the diseased structure, has the effect of hastening the separation of the slough and of destroying the bad odour. I have most frequently employed, for these purposes, the chloride of lime, or cresote, or both, in injections, consisting chiefly of mucilaginous fluids, in quantity and frequency according to the progress and urgency of the case. When the disease was very far advanced, and the use of these appeared likely to occasion inflammation of the peritoneum or adjoining parts, I have preferred to have recourse to powdered carbon, with tincture of belladonna, or extract of hemp, mixed in any mucilaginous fluid, as a vaginal injection. It has generally the effect of deodorising the discharge, and soothing the patient.

213. d. The complication of pregnancy with cancer uteri must be treated according to the peculiarities of each case; but its treatment cannot be undertaken upon at this place. It is fully considered in Dr. West's work already referred to, where the reader will also find the results of extirpation of the uterus and of its cervix very satisfactorily discussed. To this work, and to surgical writings on this subject, I must refer the reader.

214. e. The constitutional treatment of cancer uteri, or the means most appropriate to the existing cancersous cachexia, is not different from what I have advised in the articles on Cancer (see §§ 27—44.) and on Scirrrous Growths (§§ 113. et seq.). The chief objects proposed are to promote the digestive and assimilating processes, and to support constitutional power, and vital resistance to the progress of the malady. Subordinately to, and forming a part of, these may be mentioned, due attention to the secreting and excretory organs; and due watchfulness on the part of the patient, to prevent more distressing symptoms. The anaemia attending the advanced stages of the malady should also claim our attention; and chalybeate prepa-

VACCINATION. — SYNON.—*Vaccinia (from Vaccu, a cow), Variola vaccinina; Variola vaccina; Vaccina, vaccination, Fr.; Kuhpocken, Schutzblatter, Germ.; Vaccina, Vaccinations, Ital.; Vaccini, Cow-pox."

Commenced 3rd. of May. 18th. Oliver. (Author in Preface, &c.)

1. DEFINITION.—*Variola vaccinina—a vesicular disease developed in the human subject by inoculation of cow-pox, or of the lymph from the various vesicles, affecting the cow.

2. I. HISTORY OF. — It would appear, from ancient Sanscrit writings, that vaccine inoculation had been practised in India from the earliest ages, and that the preservative influence of vaccination was known, and had recourse to, in different parts of the East. Mr. Bruce, Consul at Bushire, states, that vaccination was well known in Persia for many ages. Hufnagel found among the inhabitants of the Caucasus "a peculiar method of preserving the cow from the natural and inoculated small-pox, and when he submitted this influence to the tests of experiment and practical observation. In 1776 Dr. Jenner remarked, that a number of persons in Gloucestershire could not be inoculated with small-pox; and, having become aware that there was a regular belief that persons who had been caught the cow-pox, from milking the cow, were not subject to small-pox, he was induced to investigate the grounds for this belief. In the course of his researches, and after encountering numerous difficulties and opposing opinions, which would have discouraged all but those who possessed a determined will and powerful genius, he found that the cow was subject to a variety of eruptions on the teats, all of which had received indiscriminately the name of cow-pox. He learned to distinguish between these, and ascertained that one only was possessed of a specific protective power over the human body. This he called the true cow-pox, the others the spurious. He next ascertained that the true cow-pox underwent progressive changes; and that it was only at one period of its progress, or in the acme of eruption, when it was endowed with specific or preventive, or anti-vaccinal properties. During the investigation of this branch of the subject, Dr. Jenner was struck with the brilliant idea that it might be practicable to propagate the disease by inoculation, first from the cow, and successively from one human being to another. It was not, however, until 1796 that he was enabled to take the decisive step of inoculating for the cow-pox, upon the success of which his grand scheme mainly rested. An opportunity of testing his ideas by satisfactory experiments was not afforded him until that year, when cow-pox matter in an active state was found, and parents were met with possessing sufficient confidence to submit their children to the important trial. On the 14th of May, 1796, James Phipps was vaccinated with matter taken from the hands of Sarah Nelmes. He passed through the disorder in a satisfactory manner, and was tested by various inoculation, on the 1st of July following. The small-pox inoculation took no effect. Jenner now proceeded to communicate the result of his long investigations concerning cow-pox, but delayed his work in the hope of furnishing additional proofs of the success of vaccination. These he was enabled to procure; and in June, 1796, he published, in London, his original essay, entitled, "An Enquiry into the Causes and Effects of the Variolae Vacciniae; or a Disease discovered in some of the Western Counties of England, particularly Gloucestershire, and known by the name of the Cow-pox." This work deserves a particular notice. In it Dr. Jenner states his belief that this disorder does not originate in the cow, but is communicated to this animal from the horse, where it appears on the heels, and is known by the name of the greese; the hands of farm-servants and milkers being the medium of communication. He next suggests that the small-pox itself may have been originally morbid matter of the same kind, which, circumstanced as it was, and perhaps aggraved into a contagious and malignant form. He afterwards states his conviction that cow-pox inoculation leaves the constitution for ever after secure from the infection of small-pox; and he concludes by enumerating four classes of persons to whom cow-pox inoculation holds out the prospect of great benefits:—1st, Those who, from family predisposition, may be presumed likely to take small-pox unfavourably; 2nd, persons of a scrofulous diathesis; 3rd, those who, from idiocy-synergy, resist small-pox inoculation in early life; and, 4th, those who are labouring under chronic forms of disease, in which counter-irritation is desirable.

3. At the end of July, Mr. Cline made the first experiment with cow-pox in London, which succeeded perfectly; and soon afterwards recours was had to vaccination in many places. In his second publication, dated April, 1799, Dr. Jenner judiciously recommended caution and moderation in researches into the efficacy of cow-pox inoculation; but in 1800 he expressed his conviction that the cow-pox is capable of excing small-pox from the earth; and in his fourth publication, May, 1801, he again expressed.
the same sanguine opinion. The commencement of this century was remarkable for the progress of vaccination. In 1801, upwards of six thousand persons had been vaccinated, and the greater part had been tested with small-pox. In 1800, 1801, and 1802, vaccination was introduced into France, Germany, Italy, Spain, and the East Indies. In 1802, parliament voted Dr. Jenner a reward of 10,000l. for the discovery, and, in 1807, the additional sum of 20,000l.; and in 1808 vaccination was taken under the protection of Government.

4. In 1809, Mr. Brown, of Musselburgh, published the opinion that the prophylactic virtue of cow-pox diminished as the time from vaccination increased. In 1818 and '19, an epidemic small-pox pervaded Scotland, and many vaccinated persons passed through a mild form of variola. The term, "modified small-pox," was now adopted. Dr. Moxon, in 1818, published a volume on "the different kinds of small-pox, and especially on that which sometimes follows vaccination;" and in 1820, "An Account of the Vaccination Epidemic," by Dr. T. Thomson, of Edinburgh. Between this date and 1823, when I wrote on the subject, as well as subsequently to the latter year, some very remarkable cases came before me in both public and private practice, occurring in the same and in different families, proving the impairment of the protective influence of vaccination with the growth of the body, and the lapse of time, until it entirely ceased, at least in many cases, after puberty, when vaccination was performed in infancy.

5. In 1825 the Bills of Mortality announced 1300 deaths by small-pox, among whom were several persons who had been vaccinated. Small-pox was epidemic in France in 1826 and '27, and in the northern parts of Italy in 1829; and in consequence of the numbers of the vaccinated who had been attacked by small-pox more or less modified or unmodified, the practice of revaccination commenced in Prussia and the German States, and was subsequently encouraged by their governments. This practice has more recently been voluntarily adopted by many in this country. In 1833—4, small-pox prevailed epidemically in Ceylon, when a considerable number of the vaccinated died; and it made great devastations in Hindostan on several occasions, both prior and subsequent to this date, and many of the vaccinated have been carried off by it. Dr. Gregory states that the admission into the Small Pox Hospital, in 1838, more than doubled the average number received annually, prior to the discovery of vaccination, and that two-fifths of the admissions consisted of persons who had been vaccinated. Many had the disease severely, and more than twenty of the number died. Recently, parliament has legislated on vaccination and small-pox, but in a way which is neither satisfactory to our profession, nor beneficial to the community.

6. Having now stated, from the history and certain of the results of vaccination, what has been urged against it, and having, when treating of small-pox and of various inoculation, noticed what appeared in favour of the latter (see Small-pox, §§ 104—114.), it now becomes a duty to advance to the opposite of which it has been advanced both at this place and in that referred to. The facts evincing the failure of vacci-

7. Among the more recent evidence in favour of the protective influence of vaccination, there is none which seems to deserve more attention than that which has been furnished by Dr. Balfour. His deductions have been founded on the returns of the Army, the Navy, and the Royal Military Asylum. But, although these appear very favourable, they are actually not so much so, as the data have been given by a mere glance by Dr. Thomson, of Edinburgh. Between this date and 1823, when I wrote on the subject, as well as subsequently to the latter year, some very remarkable cases came before me in both public and private practice, occurring in the same and in different families, proving the impairment of the protective influence of vaccination with the growth of the body, and the lapse of time, until it entirely ceased, at least in many cases, after puberty, when vaccination was performed in infancy.

5. In 1825 the Bills of Mortality announced 1300 deaths by small-pox, among whom were several persons who had been vaccinated. Small-pox was epidemic in France in 1826 and '27, and in the northern parts of Italy in 1829; and in consequence of the numbers of the vaccinated who had been attacked by small-pox more or less modified or unmodified, the practice of revaccination commenced in Prussia and the German States, and was subsequently encouraged by their governments. This practice has more recently been voluntarily adopted by many in this country. In 1833—4, small-pox prevailed epidemically in Ceylon, when a considerable number of the vaccinated died; and it made great devastations in Hindostan on several occasions, both prior and subsequent to this date, and many of the vaccinated have been carried off by it. Dr. Gregory states that the admission into the Small Pox Hospital, in 1838, more than doubled the average number received annually, prior to the discovery of vaccination, and that two-fifths of the admissions consisted of persons who had been vaccinated. Many had the disease severely, and more than twenty of the number died. Recently, parliament has legislated on vaccination and small-pox, but in a way which is neither satisfactory to our profession, nor beneficial to the community.

6. Having now stated, from the history and certain of the results of vaccination, what has been urged against it, and having, when treating of small-pox and of various inoculation, noticed what appeared in favour of the latter (see Small-pox, §§ 104—114.), it now becomes a duty to advance to the opposite of which it has been advanced both at this place and in that referred to. The facts evincing the failure of vacci-

8. This table is, however, fallacious, as the aggregate here given is not the actual number of different individuals, for the much larger proportion, if not the great majority, of the average number of troops in these eight years (140,720), are actually the same individuals enumerated again and again, or even for several years, unless the discharges and deaths have been remarkably great; whilst the number of cases and of deaths are the total amount furnished during the eight years from among the individuals actually serving; for it cannot be shown that during these eight years the army was formed of 1,135,940 different persons.

9. The fallacy now pointed out exists in the other tables, more especially in that giving the results as respects the Navy, and from it no correct inference can be drawn. His Report, however, of vaccination of the boys of the Royal Military Asylum, is a much more important document, and this I adduce. "Of 5,774 boys taken as

the strength of the establishment from its opening in August, 1803, to the 31st of December last (1851), 1,950 are recorded as having marks of small-pox, 3,636 marks of vaccination, and 180 no satisfactory protection was given. Of these, if in the instances in which all vaccinated on admission, there were 1,950 protected by previous small-pox, and 3,024 by vaccination."

It must be presumed that the boys leave the asylum when they reach puberty or manhood, or before this latter epoch. The results subsequently are not known, and cannot well be ascertained; and let it be remembered, that the liability to small-pox, modified or otherwise, then becomes greatest. Nor should it be overlooked, that exposure to the infection of small-pox cannot be as great in garrisons and in an asylum as in the general community. Besides, when a case of small-pox occurs in either garrisons or in an asylum, it is removed to the infirmary, or other places of seclusion; whereas among the public, with few exceptions, a case, whenever it occurs, becomes a focus of infection, from which the disease spreads in all directions amongst the unprotected.

10. There can be no doubt that vaccination, satisfactorily performed, has added a new chapter to medical jurisprudence, and seems to hold a place of importance among the arts of man. It is, however, true, that the protection against small-pox has been obtained by the sacrifice of many lives, and that the disease is still prevalent in the world, and that the cure is still unknown. Dr. Jenner’s experiments concerning it were often interrupted by its complete disappearance. Dr. Jenner at first considered that cow-pox in the cow was generally a local disorder confined to the udder; and such it has appeared to be in the last having in many instances. Subsequent observations, however, have shown that it is really a febrile constitutional disease, accompanied with eruption, although the febrile symptoms are often not very manifest. True cow-pox shows itself on the nipple of the cow, in the form of irregular pustules, or more strictly, as vesicles passing into a pustular state. At their first appearance they are commonly of a pale-blue colour, or rather of a hue approaching to livid, and surrounded by an erythematous or erysipelas-like inflammation. They sometimes degenerate into plaigedecic ulcers. The animal appears indisposed, and the secretion of milk is much lessened. The cow is subject to other pustular sores on the nipples, which are of the nature of common inflammatory sores, and possess no specific quality. They do not present any blush or livid tint, or any erysipelas-like redness around them. They desiccate quickly, and create no apparent constitutional disorder in the animal. Such a complaint is frequent among cows in the spring, when the calf is suckling. It was called by Dr. Jenner the spurious cow-pox.

12. Casual cow-pox in man is caught by milkers of afflicted cows, and appears on the hands and wrists in the form of inflamed spots, which go on to suppuration, forming pustules of a circular form, having elevated edges, and depressed centres, and are of a colour inclining to blue. After a time absorption takes place, and swellings appear in the oculi. Fever succeeds with headache, sometimes with vomiting, and in some cases with delirium. The febrile symptoms decline in three or four days; but the sores on the hands often remain, very painful and difficult to heal for a considerable time. No eruption on the skin shows the decline of the febrile symptoms.

13. III. INOCULATED COW-POX.—i. Regular Cow-pox.—When vaccination has been successfully performed on a healthy child, the pustule may be felt slightly elevated on the second day; and on the third, and even on the second, a slight effusion may be distinctly seen, by the aid of the microscope, surrounding the inflamed point. On the fifth day a distinct vesicle is formed, having an elevated edge and a depressed centre. On the eighth day it appears distended, with a clear lymph. The vesicle on this, its day of greatest perfection, is circular, and either pearl-coloured or slightly yellow. In its form and structure it resembles the pustule of small-pox. Its margin is turgid, firm, shining and wheel-shaped. It is composed of a number of cells, by the walls and floors of which, the specific matter of the disease is secreted. On the evening of the eighth day, an inflamed ring begins to form around the base of the vesicle, which continues to increase during the two following days. This area, or ring, is circular, its diameter extending from one to three inches. When at its height, on the tenth day, there is considerable hardness and swelling of the subjacent cellular tissue. On the eleventh day the area begins to subside, leaving as it advances, one or three concentric circles of a bluish tint. The
1288

VACCINATION — IRREGULAR OR ANOMALOUS.

vesicle has previously burst, and its surface acquired a brown colour. The lymph which remains becomes opaque and gradually concretes; so that about the fourth or fifth day after the vaccination, the vesicle is converted into a hard round scab, of a reddish-brown colour. This scab contracts, dries, blackens, and about the twenty-first day, falls off, leaving a cicatrix, which is permanent in after life, is circular, somewhat depressed, striated, and indented with the eight, or ten minute pits, corresponding to the remains of cells of which the vesicle has been composed.

14. Slight constitutional disturbance is observed about the seventh or eighth day, or sometimes a little earlier. The child is hot, restless or feverish, and the bowels slightly disordered; but this subsides in two or three days. A few children, however, present no sign of constitutional disorder, which is not by any means essential to the success of the vaccine process. About the tenth day a papulous eruption, of a lichenous character, sometimes appears on the extremites, occasionally extending to the trunk of the body. It continues for about a week, and often lasts after the scab has fallen off. This vaccine lichen is met with chiefly in children of a full habit, where numerous vesicles had been raised on the arm, which discharge freely. It is an accidental occurrence, which, like the constitutional irritation, indicates a full effect of vaccination on the system; neither the one nor the other however, being deemed requisite to ensure such effect.

15. In adults, vaccination exhibits the same succession of phenomena as in infants. The vesicles, however, are thinner and more easily ruptured. The lymph is usually of a yellowish tinge, and the areola is more extensive. The glands of the axilla frequently swell, which is rarely observed in children; and constitutional irritation is more frequent and greater. Secondary lichen is less frequent and less marked. Dr. Hert, of Ludwigsburg, considers that the adult lymph is more energetic than infantile lymph, but this requires further investigation.

16. ii. The irregular or anomalous vaccine vesicle.

The above normal course of the vaccine vesicle is liable to be disturbed in various ways, and by various causes. Imperfect vaccination presents no uniform sign, but exhibits different appearances in different cases, such as pustules, ulcera tions, scabs, and irregular vesicles. The irregular vesicle is attended at its commencement by urgent itching; provoking scratching or rubbing, to which the subsequent appearances are unjustly attributed. The vesicle throws out a premature efflorescence, and advances too rapidly, so that on the fifth day it has attained its height, when it will be found raised on a hard inflamed base. "It is acuminated, or conoidal, and gives the appearance of a common festering sore produced by a thorn." It is generally of a straw colour, and contains some opaque matter or pus, instead of a clear transparent lymph. The esch produced by it is small, of an amber colour, and drops off by the tenth day.

17. The causes of this abortive or irregular vesicle are not well ascertained. Sometimes the bad quality of the lymph employed may occasion the irregular vesicle, three or four children, or more, vaccinated from the same source, exhibiting the same irregular appearances. Dr. Gregory supposed that it might arise from the influence of weather or season, as he observed it in many more cases on the approach of winter than in the spring or summer. But the irregularity arises from the use of lymph, taken at too late a period of the disease. But although lymph taken after the tenth day will often fail to reproduce vaccinia, yet when it does succeed, the vesicle goes regularly through its course, and is perfectly effective in preserving from small-pox. Besides the benefit of preserving, moistened with a little Luke-warm water, will often produce the disease in all its purity.

18. Irregularity of the vaccine vesicle is sometimes attributable to a bad habit of body. "The proof is, that one child only out of many vaccinated with the same lymph, shall show the anomalous form of cow-pox. It is a singular but very important fact, that an imperfect vesicle, the offspring of a perfect one, degenerated by some peculiarity of habit in the individual vaccinated, shall sometimes reappear in all its original purity and perfection, when transplanted into a healthy, well-disposed subject.

19. In some instances the specific inflammation, or areola, is very severe, extends from the shoulder to the elbow, or even invades the trunk, requiring a recourse to cold lotions, active purgatives, and febrifuges. The vesicle, instead of scabbing in the natural way, is converted into an ulcer, discharging freely. The inflammation thus arising is, however, only temporary; and, if it has commenced at its proper period, it does not appear to weaken, or in any degree to interfere with the protective virtue of the vaccination. The vesicle about the fifth or sixth day occasionnally becomes sealy; a species of prickiness taking the place of the areola. In a few other cases true erysipelas supervenes. These anomalies deprive the cow-pox of operation all claim to protective influence. A much more frequent and successful anomaly is retarded cow-pox; the advance of the vesicle being without any apparent cause suspended. The areola does not form before the tenth or twelfth, but ultimately the process is completed, the success of the vaccination being in no degree prejudiced.

20. iii. Complications of cow-pox. — A child is sometimes vaccinated after having been infected by measles or scarlatina, and before their respective eruptions have appeared. In such cases the cow-pox is generally retarded. In a case recorded by Dr. Gregory, it was retarded sixteen days whilst the measles ran their course. Genuine chicken-pox (varicella lymphatica) will run its course along with cow-pox, without interfering with any of its phenomenon. The modifications which cow-pox undergoes when small-pox invades the system about the same time are interesting. When vaccination is performed during the incubative stage of casual small-pox, this latter being yet latent, the vaccine vesicle either does not advance, or advances tardily and imperfectly. Sometimes, however, cow-pox and casual small-pox may be seen running their full course in the same person at the same time. In no case, however, does the cow-pox so inserted modify the course of the small-pox. When the variolous and vaccine fluids are inoculated on the same day each disease occasionally proceeds, preserving its original character. In some cases, however, they
mutually restrain and modify each other. The vaccine vesicle in these is smaller than usual and irregular in its progress, while the various pustules which follow are of the kind termed variold varicella, or commonly swine-pox, stone-pox, or horn-pox (Seeatt. Chicken-pox, &c.; seq.); they are hard and shining, surrounded by little inflammation, and suppurate imperfectly; the little matter they contain being absorbed, leaving the cuticle hard and elevated, for some days afterwards. The eruption on the extremites does not pustulate, but is papulous, minute, and terminates without any mischief by desquamation. Although the eruption be modified in most cases, there is generally considerable disturbance of the constitution under the joint influence of the variolous and vaccine poisons.

21. When vaccination precedes variolous inoculation by a period not exceeding four days, both diseases advance locally. "Sometimes an eruption of small-pox papulae follows. At other times the variolous fever is slight, and unaccompanied by eruption. Under these circumstances, matter taken from the primary vesicles shall sometimes communicate cow-pox and small-pox respectively; but more commonly the variolous portion produces the skin of the vaccine vesicle." Various inoculations at any period not exceeding a week from the date of vaccination will take effect and be followed by a pustule: after that time no effect is produced.

Dr. Woodville on several occasions inoculated with a mixture of variolous and vaccine matter. The result was not to be depended upon, but in general pure small-pox succeeded. When small-pox inoculation precedes by three or four days the insertion of vaccine lymph, the vaccination advances, but after the tenth day the fluid in the vaccine vesicle becomes purulent; and in that state will communicate small-pox. Those who have undergone variolous inoculation in early life are generally unsusceptible of cow-pox. Vaccination, however, in such circumstances produces a certain degree of effect, the disorder manifesting itself in an imperfect and modified form. The fluid in the resulting vesicles cannot be trusted to produce the genuine cow-pox.

22. IV. Recurrent Cow-pox.—When cow-pox has completed its regular course, the constitution is left, for a very considerable time at least, unsusceptible of the same disorder. But this law does not obtain if the revaccination is performed at very short or at very distant intervals:—(a.) At a very short interval, or on the fourth, fifth, or sixth day after a regular primary vaccination, the vesicles of the second vaccination are accelerated in their course, so as to overtake the first crop, and the whole matrurate and scab together. The second crop of vesicles, however, is not more than one fourth the normal size, and the areola is equally contracted. Mr. Bryce (On Cow-pox, Edin. 1802) ingeniously availed himself of this circumstance, and, by testing by revaccination on the fifth day, he endeavoured to ascertain the full influence and actual security of vaccination. The plan, well known to have been extensively adopted. To obtain this test in greatest perfection, he advises the revaccination to be performed at the end of the fifth or beginning of the sixth day; and if no acceleration of the second crop of vesicles be observed, it is to be concluded that no constitutional effect has resulted from the first vaccination. The second is then to be regarded as the primary affection, which, in its turn, is to be tested by a third vaccination, and so on until we are satisfied that the constitutional effect has been fully produced. Dr. Gregory adds, that "some persons have claimed for this suggestion the highest honour, and have even considered Dr. Jenner’s discovery as incomplete without it. Dr. Jenner, however, never laid much stress upon it. In doubtful cases, it is a prudent practice, but it has been extolled far beyond its real merits. It shows the more that constitutional influence has been exerted by the primary vesicle, but it does not determine what has been the degree of such influence,—in other words, it does not show whether the constitutional effect has been complete or otherwise."

23. (b.) Revaccination at distant intervals from the date of primary vaccination, is deserving of notice. Dr. Jenner, in his original essays, stated that the human body, after a time, had the susceptibility of cow-pox renewed. Dr. Gregory describes four different effects of revaccination at distant intervals:—1st, In many cases, especially if the interval from the primary to the secondary vaccination has not been five years, the skin appears completely insusceptible to the vaccine matter;—2d, At intervals exceeding ten years, the virus irritates locally. In three, or at furthest four days from insertion, an areola of irregular shape appears around a minute, itching, acuminate, and angry vesicle. The glands of the axilla frequently swell; and in particular habits of body, especially in adult females, irritative fever is superinduced. A scab forms on the eighth day, which soon falls off, leaving no permanent cicatrix;—3d, In other cases, a vesicle forms more gradually, without either local or constitutional irritation; a slight areola succeeds, and the vesicle yields, on the seventh day, a considerable quantity of this lymph; but this lymph is incapable of propagating the disease;—4th, In this set of cases, the second vaccination runs a perfectly regular course. A circular areola forms on the eighth day, and the lymph propagates a genuine cow-pox.

24. IV. Nature of Vaccinia.—The identity of vaccine and variolous disease.—When Dr. Jenner announced vaccination as an antidote to small-pox, he was strongly impressed with the idea of the common origin of human and epizootic maladies; and, conformably with this idea, he viewed small-pox as the most remarkable malady which equally affects man and the higher animals; and that this malady, in its less malignant forms, assumes the form of cow-pox, chicken-pox, and swine-pox. This, however, had been long a vulgar opinion, and is somewhat analogous to the view I stated when treating of scarlet fever, which, I remarked, had appeared within the last three hundred years, and was derived from a similar disease in the horse. Jenner believed not only that small-pox and cow-pox were essentially the same disease, but that the former was a malignant variety of the latter, the parent malady being the small-pox. This opinion was expressed by the term variola vaccina, the name he gave cow-pox, when first introduced to the notice of the scientific community. The researches of Mr. Cullen have more recently confirmed the intimate connection Dr. Jenner contended for between cow-pox and...
small-pox; inasmuch as he has shown that the inoculation of the cow with various matter produces in that animal the true vaccine or cow-pox, and that inoculation of the human subject with the vaccine matter thus generated in the cow from various inoculation, propagates genuine cow-pox in man. He has further adduced some facts, which, however, require further investigation, but which appear to prove the origin of the cow-pox, or vaccinia, in the infection of the cow by small-pox, but with which, although it propages itself as true vaccinia;

25. The above facts, although scanty as they are, go to prove the following: 1st, That cow-pox originates in small-pox infection or contagion caught by the cow; 2d, That the infection of the cow by small-pox gives rise to vaccinia — an entity, which of itself produces a pustule of small-pox, but which cannot communicate small-pox, although it propages itself as true vaccinia; 3d, That, unlike, or differing from, variola or small-pox, vaccinia is not communicated, at least from the cow to man, or from one human subject to another, by any effusion or emanation proceeding from the infected at any stage of its course; 4th, That, like variolous inoculation, vaccination is capable, when properly conducted, of protecting from small-pox, with few exceptions, and at least for a considerable time; 5th, That the amount of evidence favors the opinion that vaccinia is a modification of variola, the modification proceeding from the virus of the latter having infected the cow, and occasioned the vaccine eruption; 6th, That the amount of evidence also favors the inference that vaccination protects, at least in many instances, from small-pox only for an indefinite time, and that the length of that time is indeterminate or indefinite; and 7th, That the duration of the protection may depend upon climate and various unascertained circumstances, and that there is reason to infer that, in such cases and circumstances where the protection fails after several or many years, the impairment of the protective influence is gradual, and progressive with the duration of time.

26. From the foregoing it will be seen that, while I believe, with Dr. Jenner, in the intimate connection of variola with vaccinia, and with chicken-pox and swine-pox; yet we have no proof that variola has sprung from cow-pox; the evidence being in favor rather of cow-pox, and the other kinds of pox being varieties or species of small-pox, arising out of the passage of this latter malady through the higher of the lower animals—more conclusively of the passage of the various morbid poisons through the cow, as respects vaccinia.

27. Such appears to be the relation subsisting between cow-pox in the human subject and in the cow and small-pox; it may next be inquired what connection exists between vaccinia in the cow and the vaccinia in horses. Dr. Jenner believed that they are both identical, and that cow-pox never occurs in dairy districts, except when there is access to horses; he thereby denied the spontaneous origin of the disease in the cow. Later observations have, however, proved not only the identity of cow-pox and vaccina, but have shown, at the same time, that cow-pox may exist in the cow without access to horses; and, secondly, that cow-pox is communicable to man from the horse without the intervention of the cow, and with nearly equal facility as from the cow itself. Dr. Gregory states that this branch of the theory of vaccination has been investigated with great diligence, and seems to be radically in human subjects. Amongst other observations, Mr. Crell states that he went to examine some cows affected with cow-pox; and that his proprietor, Mr. Pollard, "at the same time, expressed his conviction, that his cows had been infected from human small-pox effluvia, to which he considered they had been exposed."

28. V. PROTECTIVE INFLUENCE OF COW-POX—This subject has occasioned much discussion during the last quarter of a century, and more especially during the last five years; and the amount of protection which cow-pox affords against small-pox has been often entertained, but as yet by no means satisfactorily ascertained. In a. There are various circumstances which render it most difficult to determine this question; for the idiocy as a of some individuals seems to oppose infection by the vaccine virus, either for a time or through life; and, if such an insusceptibility of the disease be admitted, it may be further inferred that, in others, the insusceptibility being less, the vaccine infection may be incomplete, and the protection afforded be proportionately imperfect. It may be conceived that, where the disposition, in its union to receive the vaccine infection is either wanting or incomplete, the protection must be equally deficient; and hence, to estimate the protective influence of vaccination, it must be considered, that the process has not been duly completed, and that no protective influence can be claimed from it, unless the vaccine virus is received and the local phenomena proceed regularly, and leave
a ciatrix, as described above. But, independently of the indisposition of the constitution to receive the vaccine disease, or of the disposition to receive it imperfectly, the health of the individual, and the state of the season or weather, may render vaccine infection either abortive or incomplete. It has been proved that attempts have often failed that have been made to vaccinate in hot countries, and in the warm localities of temperate climates, during hot and dry states of the atmosphere; and a similar temporary insusceptibility to small-pox inoculation, during the same state of the atmosphere, has been observed. The impaired health of a person also may render him insusceptible of vaccination, until his health is restored; and various uncertain circumstances may have the same effect, either permanently or for a time. It may be inferred, all things being considered, that, where an insusceptibility to vaccination exists, an equal indisposition to small-pox may be expected; but, as a rule, there may be many exceptions to this, and it would be unwise to confide in it.

29. Besides circumstances more immediately connected with the individual, there are others depending upon the virus itself. The vaccine infection may be destroyed by long-keeping, or by a warm and humid, or a very warm and dry atmosphere, if it be even for a short time exposed to these states of the air. It may also be either inert, or imperfect in its operation and constitutional as well as local effects, owing to its having been taken from the vaccine vesicles at a too early, or a too late stage of the process of maturation, as already noticed (§ 17); or even to its having been too long kept, or to its insufficient protection from the action of the atmosphere. The manner in which the inoculation of cow-pox is performed — or the efficient or imperfect operation of inoculation — may in some way also affect the results. The number of the incisions or punctures, and the actual deposit of the virus within the sphere of the action of the absorbents or veins, may not merely produce either a full and satisfactory effect, or no effect at all, but also an imperfect or an insufficiency protective effect.

30. Imperfect vaccination has been referred to a variety of causes. It has been very generally supposed that the vaccine virus becomes deteriorated by its passage through numerous human bodies, or that the protective influence is weakened by the length of time, and the long succession of subjects through whom it has been perpetuated, from its direct inoculation from the cow. Of this, however, there appears to be insufficient proof. It has been remarked, that persons who have been vaccinated by Dr. Jenner himself, before deterioration could possibly have commenced, have nevertheless been attacked by small-pox in after-life. A recent writer remarks, that "so far from believing in any deterioration of virus from successive inoculations, there is reason to believe that, by a careful selection of well predisposed children, the pock may even be restored from an imperfect to a perfect state, and by proper care, the disease may be obtained happily in that condition. If children be successively vaccinated from each other, all of whom are from various causes ill disposed to take on the perfect disease, the virus may unquestionably degenerate, and at length wear out altogether. In tropical countries, and in confined localities, such an occurrence certainly takes place, but this is very different from the notion of a virus deteriorated by the mere influence of time."

31. d. Imperfect vaccination, as a cause of failure of protection from small-pox, was much insisted on by Dr. Jenner. Vaccination is said to be imperfect when, not knowing the considerable deviation from the ordinary course of the vaccine vesicles takes place. The deviations from perfect vaccination are imputed to one or more of the following causes: — 1st, To spurious matter, or matter taken from the arm at an improper period of the process; — 2d, To an insufficient number of vaccine vesicles; — 3d, To preoccupation of the skin by some disease, in which a fluid is exuded capable of conversion into a scab, such as tetter, scald-head, ringworm, erysipelas, &c.; — 4th, To robbing the vesicle ineffectually of its contents, particularly when one only has come to maturity; — 5th, External violence done to the vesicle, as rubbing or scratching it, especially during its early stages. That cause may, and often do, interfere with the success of the vaccine process, cannot be doubted; but the influence imputed to them cannot be determined; for it has been proved, by very few instances, it, should be admitted, that vaccination, which, according to all indications, should have been considered perfect, has afforded only imperfect, or only temporary security; whilst, on the other hand, cases in which one or other of the above causes has interrupted the regular process, have notwithstanding afforded perfect security. The instances in which single vesicles have preserved from small-pox, both casually and by inoculation, Dr. Gregory states to be so numerous that no reliance can be placed on the notion which would connect the security of the individual with the number of maturing vesicles. A case of small-pox after vaccination will sometimes occur in a member of a family, all of whom have been vaccinated in the same manner, by the same practitioner, and having similar marks on the arm, and equally exposed to contagion, that one alone having become infected. It should also be recollected that vaccination under the same circumstances, especially of the members of the same family, may, upon exposure to small-pox infection, be followed by this malady, in its various degrees of modification, according to the time that has elapsed from vaccination. It has even been ascertained, that persons have caught small-pox after having been subjected to Bayon's test of the perfect constitutional affection of the original vaccination. It should, however, be recollected that these are merely exceptions to the general rule of protection; and as exceptions have attracted greater attention than these which prove the rule.

32. e. The presumed decadence of vaccine influence and protection has been believed by many from an early period of the history of vaccination. Dr. Jenner, in his third publication, in 1800, remarked that there were some "who suppose that the security from small-pox, obtained through cow-pox, will be of a temporary nature only. This supposition is refuted not only by analogy with the habits of diseases of a similar nature, but by incontrovertible facts, which appear in great numbers against it. That analogy may be considered opposed to this supposition may be allowed, although the analogy is neither very close nor very conclusive."

"Vaccination — Protective Influence of."

Page 1291
facts opposed to it were certainly neither strong nor very manifest, inasmuch as time, the necessary element of their manifestation, had not then elapsed. Dr. Jenner was, however, convinced, or at least most sanguine in this matter, is shown in his petition to Parliament, where he states that his discovery had the "beneficial effect of rendering, through life, the person inoculated with it perfectly secure from the infection of small-pox." He rested his arguments as to the permanency of the protection in his belief, which subsequent researches have proved to be well founded, in the identity of vaccinia and variola; but, even granting the identity, a very marked modification of the former from the latter, by the passage of the poison through the body of the cow, must be admitted, the result being the conversion of a frequently malignant and generally severe malady into a mild disorder. Are we, therefore, from the mere admission of identity thus modified, to infer protection by means of the milder form of disorder? May it not be as justly inferred, that whatever protection is given by the morbid affections of the disease may possibly be sometimes overcome by the contagion of the more severe malady? and that the protection of the former, being weaker or milder than that furnished by the latter, may not be so enduring, especially in some constitutions and circumstances, and more particularly if the process of vaccination has not been perfect or complete in all respects.

33. It was admitted by Dr. Jenner, Dr. W İl lan, and others, who believed in the permanency of vaccine protection, that, when the vaccine process has been imperfectly gone through, and when, from some peculiarity of constitution, the system receives only a portion of, or is insufficiently imbued with, that protective influence which cow-pox is capable of imparting, then "small-pox would recur, and thus the degree in which its phenomena were modified was proportioned to the degree of perfection of the vaccine vegetable assumed during its development."

34. This partial protection from small-pox, admitted in the circumstances just stated, has, however, been extended by many to the more perfect processes of vaccination; and there are many medical men and others, who believe that the protection is complete only for seven, or ten, or fourteen, or twenty-one years; but that the small-pox caught after vaccination is modified in proportion to the shortness of the time which has elapsed from vaccination; and that, after the longest of these periods, little or no modification is observed. This opinion has manifestly been pushed too far; for it cannot be correctly inferred, that these facts, which have undoubtedly been often observed, especially in certain families and persons, in whom peculiarity of constitution, irregularities or imperfections in the vaccine process and other circumstances, tending to account for the imperfect or non-permanent protection, by any means prove that such imperfect protection exists in all cases, or even in a very large minority of cases. The circumstances which secure the desired protection, or which weaken it, or even destroy it altogether, are as yet not known with sufficient precision, and we are as much at odds as different opinions, being undetermined on this very important matter. It need only be inferred that the vaccine process should be studied, so as to secure its perfection as far as possible, and in this state that it should be generally practised with the belief that it is a safe and permanent, or an universal, or always a permanent protection from small-pox, it nevertheless proves a permanent protection in the great majority of instances, and that, where the protection fails, it renders in the vast majority the small-pox a comparatively mild disease.

35. It has been attempted to calculate the proportion of the vaccinated who take small-pox. On this topic it is impossible to arrive at any approximation to the true result. The degree of severity of a small-pox epidemic, occurring in a community containing many vaccinated persons, may be expected to influence the result. Dr. Croose, in his account of the variolous epidemic of Norwich, in 1819, stated "that of the vaccinated, not more than one in twenty will be in any way affected by the most intimate exposure to small-pox contagion; and less than one in fifty will have the disease in a form answering to the generally mild and uneventful variola small-pox." These calculations may have been justified by the epidemic in 1819; but they cannot be viewed as applicable to other circumstances, and more especially to later periods in the history of vaccination and of small-pox prevalence. This is one of the many instances in which statistics cannot be confided in when applied to disease.

36. VI. SMALL-POX AFTER VACCINATION. — I have adverted to this topic when treating of Small-pox (§ 38.), but I may make a few remarks respecting it which were then omitted. Variola, as it occurs after vaccination, is generally a mild disease. The pustules are usually small, hard and tuberculated, few of them maturing perfectly. Yet the small quantity of matter they do contain commonly produces small-pox in others; and the exhalation from the affected also communicates the disease. This modified state or variety is not usually followed by pits or scars. Cases of much greater severity do, however, occur, and even assume the worst or confluent forms, or terminate fatally, as I have observed on several occasions. In some instances, a fatal termination may be imputed to the accompanying or secondary fever of small-pox attacking a delicate or scrofulous frame — or persons advanced in life, of a plethoric habit, or affected by some visceral disease, — or those predisposed to, or actually labouring under, pulmonary or other maladies. In such cases the physician perceives the true source of the fatal result, whilst the friends of the patient impute the event to small-pox. Soon after vaccination was introduced, cases of failure were imputed to imperfections in the vaccine process in these cases; and not unfrequently the varioloid disease which followed was so slight as to induce doubts of its nature; and very probably there were sometimes grounds for entertaining the scepticism. But, with the lapse of time, facts, proving the failure of the protective influence, became more numerous, and were observed most frequently amongst adults. Dr. Gregory, who was for many years physician to the Small-pox Hospital, states that many of the patients who had been received into the hospital under such circumstances (after vaccination); and these few
have invariably had a mild disease, more allied to
chicken-pox than to small-pox; whereas all the se-
vere cases, and the greater proportion of the mild
ones, have occurred in adults, in whom an interval
varying from 10 to 30 years (the average eighteen)
had elapsed since the date of vaccination."

37. VII. Operative Measures. — A. The
performance of vaccination although a simple is a nice operation, requiring much attention
to several circumstances. Care should be taken
to avoid a failure, as it often causes a delay,
or a neglect of the repetition of the opera-
tion. Failures arise chiefly — 1st, From the
selection of the lymph; 2nd, From the mode of
operating; and 3rd, From the constitution or
state of health of the individual operated upon.

— a. The vaccine lymph should be recent, if it
can be obtained in this state. It should be per-
fectly clear and limpid, and the earlier it is
taken from the vesicle the better. Lymph may
be taken with every prospect of success after the
fifth day, and up to the eighth or ninth days.
That taken on the tenth day should not be con-
fined in. When vesicles are too often or too
roughly opened, the glassed, the glassed, the
serum of the blood may commingle with the
lymph, and impair, or even altogether destroy,
the efficacy of the latter. A vesicle should always
be treated gently. — b. The lancet used in
the operation ought to be clean and sharp. A
vac-
cinating lancet should have a broad shoulder, as
well as a sharp point, to enable it to retain an
adequate portion of virus. The skin should be
kept tense during the operation, and six or eight
punctures be made at convenient distances from
each other, and to a slight depth. Provided that
a genuine lymph of due intensity comes in con-
tact with the absorbing surface of the cutis vera,
it matters not whether much or little blood flows
from the punctures. The quantity of blood that
escapes depends more upon the child’s habit of
body than upon the operator. A lethargic child
generally bleeds freely when vaccinated, but
generally exhibits the most notable signs as to the
effect. — c. The child operated upon should be in
perfect health. Vaccination ought to be delayed during the existence of any
disease — at the period of dentition — when the skin is
affected by any eruption — or when the digestive
canal is disordered — unless some pressing occa-
sion should require it. The best age for vacci-
nating is between the third and fifth month after
birth, before dentition has commenced.

38. B. Preservation of vaccine lymph. —
Fresh lymph should always be preferred when it
can be obtained; but there is often no other
resources than preserved lymph. Being liable to
spontaneous decomposition, as well as to other
changes too slight or delicate to admit of demon-
stration, unless in its effects after inoculation,
and either impairing or destroying its efficiency,
great difficulty has been experienced in preserving
it, and more especially in transmitting it to tro-
phant parties. Dr. G. de Lavoisiers states the
following to be modes of preserving lymph which are now adopted: — 1. It may be
preserved fluid for several days between two
pieces of glass, about an inch square, which fit
each other accurately. When dry, the lymph
will often, if carefully moistened by the breath,
propagate the disease. — 2. Vaccine lymph may
be preserved on ivory points, shaped like the
teeth of a comb. These should be twice dipped
in the fluid of the vesicle, and allowed to dry
slowly. They should be retained, when used,
in the wound on puncture for about half a
minute. They are considered very effectual. —
3. The lymph may be kept in a fluid state in
capillary tubes, having a bulb at one end. They
admit of being hermetically sealed. But to
prevent spontaneous decomposition the lymph
should be collected in minute quantities only.

Mr. Bayes, in 1802, stated that vaccine
scabs may be used for communicating the disease,
and it has been ascertained that this is the most
certain mode of transmitting cow-pox to warm
climates. When about to be used they ought to
be rubbed to a powder, and moistened with
a little tepid water. When thus reduced to the
consistence of this mucilage, they form an arti-
ficial lymph. Punctures should be numerous
where the lymph is employed. — 5. Dr. Jenner
occasionally used doses of lint, saturated with
the fluid of an eighth day vesicle. These he
placed between glasses, one surface of which had
roughly, and the other glassed, the glasses put
gether, their edges sealed, and the whole covered
with sheet lead. Preserved in this manner
vaccine lymph will retain its fluidity and effi-
ciency for a considerable time.

39. VIII. Revaccination. — The phenomena
presented by revaccination after comparatively
short intervals, have been noticed (§ 253). It, how-
ever, becomes necessary to take a brief survey of the
practice of this measure after long intervals, with
the view of affording a complete protection against
small-pox. It having been believed by many me-
dical men, and it having become the popular belief,
in several countries, that vaccination, however
completedly performed, is weakened in its protec-
tive influence by the lapse of time, or growth of
the frame, a recourse to revaccination has been
had, in some countries to a great extent. Dr.
Goldoni, in 1804, first announced this doctrine,
but assigned the revaccination to be performed
three or four years for the decadence of protection.
In France, M. Caillot, Boulc, Berlan, Gen-
ouil, and others both in this and in other coun-
tries, supported this opinion, but assigned much
longer periods for this occurrence, the time as-
signed by them varying in the opinions of each
from ten to twenty-four years, but they all agreed
in believing that the loss of protective power was
gradual and progressive. M. P. Dubois
endeavoured, in 1825, to refute this doctrine as a
general inference, although he admitted the facts
upon which the opinions of those physicians were
founded. The epidemic prevalence of small-pox
soon afterwards in France, Germany, and Den-
mark, confirmed, by the numbers of vaccinated
attacked, the opinion that vaccination lost, after
the lapse of a number of years, its powers of pro-
tection from that malady. From this period —
about 1829 — revaccination began to be practised
on the Continent, in France, Germany, Sweden,
Denmark, Prussia, and in France. In 1833, it was adopted in the Prussian army,
and was performed on 48,047 persons, and was
successful in 15,269. In 1834, 16,673 successful
cases were obtained in 44,454 operations. In
1835, 16,316 were successful in 39,192 revaccina-
tions. In 1855, in 42,328 revaccinations.
VACCINATION.—BIOGRAPHY AND REFERENCE.

18,136 fully succeeded, and 9,040 presented an irregular form of the eruption. Of 14,048 persons vaccinated from recrudescence, 1,569 were successful on the repetition of the operation for the second time. In 1839, 41,481 soldiers of the Prussian army were revaccinated; of this number, the cicerettes of the first vaccination were distinct in 33,325, imperfectly distinct in 5,899, and not detected in 3,597. The revaccination succeeded in 19,249, and was imperfect in 8,534. Similar results have been obtained from revaccination in several of the German states, in Hanover, &c., between the years 1835 and 1842. In France, revaccination has not been much practised, and in England still less. During the reign of Louis Philippe, the Royal Academy of Medicine of Paris was consulted respecting the propriety of having recourse to revaccination. This body were opposed to this measure, as they believed that it would weaken confidence in vaccination. M. Delenmeres protested against this decision, and was succeeded, followed by MM. M. Flard, Hardi, Pressat, and others, who published memoirs on the subject in the French journals. M. Villaret, in 1843, practised revaccination in 401 soldiers of the 7th regiment of dragoons; it was successful in 307; and in 153, who had formerly had small-pox, the operation fully succeeded in 97. In a second series of 447 persons, who presented perfect vaccine cicatrices, 402 had cow-pox a second time; and, of 123 persons marked by small-pox, 89 presented a successful vaccination. MM. Bocquet, Flard, Guersant, and Blache, who, in 1826, expressed their belief in the permanent security furnished by cow-pox inoculation, have subsequently altered their opinions, and have practised revaccination in numerous cases; and have strenuously advised this measure, as the only certain means of preventing small-pox, by sustaining the prophylactic influence of vaccination.

40. In 1845 the Academy of Sciences of Paris published a Report, containing the following conclusions:—1. The protective influence of vaccination is complete as regards the great majority of the vaccinated, and temporary as regards a small number only; and in these latter it is almost absolute up to the period of puberty.

2. Small-pox rarely attacks the vaccinated on being ten or twelve; and it is from this age to thirty or thirty-five that they are chiefly exposed. 3. That in addition to its preservative influence, vaccination endows the constitution with an influence which renders the symptoms of small-pox much milder and of shorter duration. 4. Cow-pox, directly or recently derived from the cow, is attended by a much more intense local phenomenon, and by a more certain and permanent effect than that which has passed through a great number of human subjects; this intensity of local action subsiding after many successive vaccinations. 5. The preservative influence of vaccination appears not to be intimately connected with the intensity of its local effects; nevertheless, in order to preserve the properties of vaccinia unimpaired, it is prudent to renew it as frequently as possible from the cow. 6. Revaccination is the only means we possess of diminishing the chances of success of vaccinia from the least complete grades of protection. 7. Revaccination, however, is not certain evidence that the vaccinated in whom it had succeeded would have been destined to contract small-pox, but merely that it was probably among the latter malady was most likely to appear, if they became exposed to its infection. In ordinary times revaccination may be practised after fourteen years; during epidemic small-pox it may be practised after a shorter period. 8. It would seem, from the circumstances of so many persons having presented the regular vaccinia after small-pox (§ 30.), as stated above, that the complete development of the local action after revaccination cannot justly be viewed as a certain proof that the successfully vaccinated could have been infected with small-pox, although they might have been infected if they had been exposed to the more concentrated sources of infection. Nor can successful revaccination, nor its failure, be viewed as absolutely indicating a state of constitution, which shall resist the infection of small-pox on all occasions, more especially when this malady supervenes in an epidemic form, although it may resist this infection on nearly all occasions, or with very few exceptions; these exceptions, however, being a mild or modified small-pox, in the great majority of instances.

VAGINA AND VULVA—DISEASES OF THE.

1. VAGINA AND VULVA—DISEASES OF THE.—Affections of the vagina and vulva are as frequently surgical as strictly medical. As, however, certain of them require internal or constitutional means, either altogether or chiefly, in their treatment, they may be viewed as belongs to the latter category, although we can see no just reason for separating the two departments of practice, or for assigning them more to the one than to the other.

2. I. THE VAGINA is liable to several congenital alteratons, or vices of formation. The chief of these are:—1st, Its opening in an abnormal situation;—2d, Its partition by a portion into two canals;—3d, Its imperforation;—4th, Its constriction;—and 5th, Its entire absence. As to either of these, I can add nothing to what will be found in the many excellent recent works on surgical pathology. The best of these conditions is of great importance as respects the diagnosis, and the results proceeding from it. It may become the subject of medical investigation as respects especially the retention of the江山, and the propriety of an operation, on this account, after due deliberation. The absence of the vagina may be only partial; but even in this case, and when the exact state is ascertained, the question as to the propriety of attempting an operation for the establishment of the canal should not be entertained, unless there is a present occasion for having recourse to it, as it may compromise the life of the patient. But what occasions may suggest recourse to a surgical operation in such cases? These are:—1st, Excessive uterine distention from an accumulation of the menstrual fluid;—2d, The superintendence of mitrites, or parotis, or both; and 3d, Contamination of the circulation from the absorption of a portion of the retained and altered blood from the uterus. This operation has been, therefore, performed successfully by C. A. B. B. V. D., D. P. C. B. E., W. L. M., L. L. M., and P. T. E. M. (VIEUX, Médécine Opératoire, l. t. v. p. 350.) The accumulated menstrual fluid may be discharged, in the urgent circumstances just stated, by puncture either by the rectum or by the bladder.

3. The diseases and organic lesions to which the vagina is liable, are inflammations, ulcers, constrictions, or contractions and obstructions, tumours of various kind, polypi, fistula, cancer, prolapus, wounds, laceration, hernia; and the impotence of foreign bodies. Several of these belong more to the province of the surgeon than to the physician, or rather require surgical, in addition to medical means.

4. I. INFLAMMATION OF THE VAGINA.—SYNON. EPHIDRIS, VAGINIS, Fr.

CLASSIF. — III. CLASS. V. ORDER (author in preface).

DEPIT. — Heat, soreness, or pain, in the course of the vagina, sometimes attended by increase of pain, or by uneasiness upon sitting down on a hard seat; and always by pain and tenderness on vaginal examination, and by a whitish, or a mucous-purulent, discharge, with slight febrile disturbance, increased or returning at night.

Inflammation of the vagina rarely occurs, unless in connection with inflammation of the vulva, or with inflammation of the neck of the
uterus; most commonly with both, unless it be
cau's by violence, by excessive sexual indul-
gence, by irritating injections, and by foreign
bodies, as pessaries, &c., lodged in the vagina. It
commonly presents an acute or sub-acute form,
whether simple or thus complicated; but it is
also often chronic, especially when it is associ-
dated with disease of the neck or body of the uterus, and
in many cases which are commonly viewed as
simply those of leukorrhea. In these chronic and
sub-acute cases, the mucous follicles of the vagina,
and often also of the cervix and vulva, are more
or less implicated—either partially or chiefly.

7. A. Acute vaginitis rarely occurs in a
simple or sthenic form, unless when it is specific,
or gonorrhreal. In rare cases, also, it is asthenic
or diffusive, owing to the occasions about to be
mentioned. Acute sthenic vaginitis, and the sub-
acute states, are most frequently consequences of
the causes just stated, or of sitting on cold or damp
seats, especially during, or soon after, the men-
strual period. I have seen it be-
tained, by some physicians, vaginitis cutanea, or
cutaneous inflammation of the vagina, especially
in its slighter or sub-acute state. In this state, it
is not infrequently met with in pregnancy, and, in
rare instances, as a complication of hemorroids.
If these simpler forms, vaginitis is attended by a
capricious whiteness, or greyness, or nearly colourless,
mucous discharge, which soon passes into a muco-
purulent and yellowish matter, especially when re-
tained for some time in the vagina; there are also
soresness and tenderness in the course of the va-
gina, sometimes with frequent micturition and
slight dysuria. I have met with several cases, in
public and private practice, of this form of vaginitis,
as a sequela of measles, but much more frequently
of scarlet fever, especially in children among the
lower classes.

6. B. Acute and sub-acute vaginitis is often
mistaken for gonorrhreal vaginitis, or the leukorrhe-
agia of French pathologists, especially of M. Raton
and his disciples; and it is generally very difficult
to distinguish between the simple and specific
forms of the disease. Generally, however, the
latter, or gonorrhreal, is attended by characteristic
signs referable to the vulva; by itching, smarting,
or stinging pain in the vagina; by frequent pains,痛
micturition, by inflammation and swelling of the
labia minora and urethra; pain and soreness
being greatly increased when sitting. The local
signs and febrile symptoms are more acute, and
the swelling, tenderness, and intolerance of an
examination are greater, than in the non-specific
states of vaginitis, and the discharge more copious
and more completely purulent. In all the cases
of gonorrhreal vaginitis which I have seen the
disease extended to the uterus, and in three to the
ova. In this form of the disease, the history of the
case, especially with reference to the affection of
the vulva, and the probability of its being
caused by an impure connection, will much assist
the diagnosis. In most of the cases which I have
seen, the disease was communicated by the hus-
bands of the females affected, the fact of this hav-
ing been the cause having been acknowledged by
the former. In some instances, much difficulty
has occurred in the diagnosis, especially when
vaginitis has been produced soon after marriage,
in consequence of excessive sexual indulgence,
and of the states of both the male and female
organisms previously, and even of the constitution
and habit of body of the females. A similar diffi-
culty is sometimes met with in the vaginitis, folli-
cular or mucous, which occasionally appears
during pregnancy. In both these circumstances,
the discharge may infect the husband, in such a
manner as to be distinguished with great difficulty,
or not at all, from gonorrhoea in the male.
The urethritis cannot be produced as a mere condi-
tion somewhat different from the specific disease, as
far as my observation of a few cases enables me to
state. The earlier signs referable to the opening
of the urethra, and the disturbing chordee charac-
terizing, are either wanting, or are slight in the
simple urethritis; whilst micturition is neither so
painful nor so difficult as in the specific disease.
The inflammation, however, of the former is more
designed to extend to the mucous surface of the
urinary bladder, and less disposed to affect the
testicles, than that of the latter malady.

9. C. Asthenic vaginitis, or diffusive inflamma-
tion of the vagina, has been hitherto unnotice-
red. I have referred to two instances of its
occurrence associated with adynamic dysentery
in married females, when treating of uterus (see
art. Uterus, § 54.), the inflammation hav-
ing extended from the vulva to the vagina and
uterus; and having been produced by the septic
and infectious exhalations evolved, during a long
continuance of warm weather, from full, open
privies. In these cases, the vaginal discharge was
mucous-purulent, streaked and discoloured with
blood, and rusty, at times of a brownish, or greenish
brown hue, and very abundant, with remarkable
swelling and tenderness of the parts, and with
the symptoms accompanying acute metritis (see
Uterus, §§ 55, et seq.). The pulse was rapid, weak,
small, and compressible; the vital prostration and
the other symptoms of adynamia being so marked
as to require powerful tonics and restoratives.
Recovery ultimately took place, but after a very
protracted illness. This form of Vaginitis may be
complicated with asthenic dysentery, as observed
in the cases now referred to.

10. D. Phlegmonous inflammation may attack
the connecting cellular tissue of the vagina, espe-
cially that between the vagina and rectum, and
occasion a small abscess between the vagina
and rectum, or even a fatalous communication
between the vagina and rectum. When the
inflammation begins to affect the cellular tissue
of the vagina and its immediate vicinity, and oc-
curs, not silent between the vagina
and rectum, the opening into either part is gen-
erally followed by quick recovery, unless the sit-
tuation be in fault, and then ulceration, or a fas-
tulous communication between the vagina and
rectum may result.

11. E. Consequences of Vaginitis. — a. Con-
striction and Obliteration of the vaginal canal is
seldom observed, the latter especially. Either of
these lesions may, occasionally, succeed vaginitis,
when inflammation caused by injuries, wounds, lacerations,
ulcerations produced by pessaries, foreign bodies,
and irritating injections; but contractions in va-
arious grades and extent are much more frequent than obliteration, which is a very rare occurrence. Injuries or lacerations during delivery are the most frequent causes of these lesions. The injection of irritants and stimulants to provoke abortion has in a very few instances been recorded as causing laceration and destruction or obliteration of the vaginal canal. These changes may occur in any part of the canal, but most frequently in the part next to the vulva, unless when they are caused by malignant disease, and then they generally commence in the cervix uteri, and extend to the portion of the vagina adjoining, and progressively to more or less of this canal. In the Article Uterus (§ 205.) I have mentioned a case where nearly the whole of the vagina was obliterated by cicatrization consequent upon a rare instance of the spontaneous cure of malignant disease of the cervix uteri and vagina. Similar occurrences have been noticed by Rokitansky.

12. b. Chronic inflammation, limited or more or less extended, sometimes either follows the acute and subacute states of vaginitis, or occurs primarily, but much more frequently as a consequence of the irritation caused by morbid secretions from cervix and vagina, from the internal or external surface of the cervix or body of the uterus, and it is often complicated with inflammation of the cervix. This form of the disease may occur either in the puerperal or in the non-puerperal state, and it may, moreover, be complicated with, and then be masked by, the uterine disease, or by inflammation of the vulva, or by the leucorrhoeal discharge, with which it is attended, both in its simple and complicated forms. Chronic inflammatory irritation, thus originating and related, may be followed by organic changes of an important nature, especially when it in particular affects the mucous follicles, or extends to the connecting cellular tissue. In such cases, ulcerations, and even perforations, of the vagina are not very rare occurrences. The ulceration may be common, serofulous, syphilitic, or chancreous. The first of these usually occurs in consequence of inflammation, chiefly of the phlegmonouscharacter noticed above (§ 10. et seq.) and commences either in the mucous follicles, or in the connecting cellular tissue. In these follicles, serofulose ulcerations may also commence, or be chiefly seated. These latter have been well described by Dr. Carew; and Dr. Hooper states that these ulcerations assume the character of scrofula in other parts. ‘The sides of the ulcers are tumid; solid puriform depositions are found about them in the cellular structure between the membranes; and there are perhaps fistulous communications with the urinary bladder, rectum, or penis muscle.’ Common and serofulose ulceration may be developed either primarily or consecutively in the lacunas and glandular bodies with which the lower part of the vagina is so abundantly supplied. When these glands are primarily affected, there is generally an abundant milk or cream-like discharge from the vagina, constituting a form of leucorrhoea, and depending upon chronic irritation or inflammation of them. This state of morbid action when prolonged, especially in cachetic or serofulose constitutions, may go on to ulceration, or even to fistulous perforations. Disease of these glands, and chronic inflammation of the vaginal surface, may also be developed or perpetuated by the morbid secretions from an inflamed or otherwise diseased cervix uteri, or internal surface of the uterus, or of its cervix. The most extensive ulcerations and perforations with fistulous communications with adjoining parts are produced by pessaries or other foreign bodies lodged in the vagina. Syphilitic ulcerations of the vagina are noticed in the articles on Cancer of the Uterus and on Venereal Diseases.

13. Complications of Vaginitis.—Acute or chronic vaginitis may be associated with inflammation of the cervix uteri, or with vulvitis, or urethritis, or even with two or all of these. It is chiefly in girls under twenty that the complication with vulvitis is observed. In some instances of this complication, an abscess forms in the labia majora, especially when inflammation of the vagina and vulva is severe; and when the inflammation extends to the subjacent cellular tissue of the coitie habits, phagedena of the parts may supervene. Gonorrhoeal vaginitis is generally associated with urethritis and vulvitis, and often also with sympathetic bubo, this latter being the consequence of inflammation of the lymphatic vessels and glands. Vaginitis is, in some cases, complicated with more or less, or even rarely, also with inflammation of the uterine appendages, especially when it is of a specific kind, as noticed above (§§ 8, 9.) In this complication the inflammation may originate either in the uterus, or in the vagina, and extend to the other parts. Vaginitis may also occur during pregnancy, and disappear after parturition.

14. ii. Treatment.—The treatment of the non-specific or common states of inflammation of the vagina is generally simple, and is locally and constitutionally antiphlogistic. In severe attacks, leeches should be applied to the upper parts of the thighs, or to the groins, or perineum, and the bleeding be promoted by warm fomentations, &c. Tepid or warm baths, general or local; cold, tepid, or warm injections into the vagina; cooling aperients, and cooling diaphoretics, and an antiphlogistic regimen, are the chief means of treatment, especially in the more acute cases, and in the early stage. Aperients which promote or excite the large bowels should be avoided; and those injections, saline and vaginal, which produce a cooling and an emollient effect, not only on the large bowels, but also on the vagina, should be selected. The injection of cold or tepid water into the vagina washes away the morbid secretion, which by remaining even for a short time, and accumulating in this part, increases or perpetuates the inflammatory irritation. Several medicated injections, either emollient, astringent, or anodyne, may also be prescribed. When the irritation, tenderness, pain, is extreme, bile, milk, and water, linseed tea, decoction of marsh-mallows, either tepid, or cold, may be administered, with a little syrup of poppies, and with either a small quantity of the nitrate of potash, or of the bichloride of soda. If the inflammation be severe, the emollient injections may contain either these in some what larger quantities, in small quantities of hypochloride of ammonia. Or instead of these the decoction of poppy-heads may be employed, with the saline substances just mentioned, or simple water with the acetate of lead and a few drops of laudanum.

15. When the more acute, and severe symptoms are
symptoms have subsided, then the more energetic astringents may be prescribed, such as the sulphate of alumina, the sulphate of zinc, acetate of lead, solution of the nitrate of silver, decoction of oak bark, and solution of tannin. Dr. H. Birkway states, that the first three he generally uses in the proportion of a dram to a pint of water, increasing or diminishing the strength according to circumstances; and after much experience he concludes that alum is the most efficacious of all these agents, with the exception of nitrate of silver. In order that injections may be efficacious, they should be administered abundantly, frequently, and with such appliances as may allow them to remain for some time in the vagina.

16. For gonorrheal vaginitis, the antiphlogistic treatment advised for the early stage of common or simple vaginitis should be energetically prescribed, and cooling diaphoretics and aperients, with demulcents, emollients, and diluents, freely used. The irritation of the urinary bladder and urethra, and the associated vulvitis, will be most surely allayed by these means, aided by fomentations, warm local and general balsam and by the emollient and antiseptic injections advised above (§ 14.). The patient should partake freely of mucilaginous diluents containing the nitrate of potash or of soda, and the carbonates of the fixed alkalies, with very small doses of camphor. After the acute symptoms have been subdued, the more astringent injections mentioned above may be resorted to. If gonorrheal rheumatism should occur, it is seldom observed in females, the treatment for that species of rheumatism, advised in the article Rheumatism (§ 163.), should be directed. Gonorrheal vaginitis extending to the cervix uteri, or occasioning endometritis, requires the means advised for this complication in the article Uterus (§ 124.).

17. Asthenic vaginitis, in the form which I noticed above, as having fallen under my observation, requires a frequent recourse to vaginal injections. Those which I prescribed consisted of alum, or of sulphate of bismuth and laudanum; the decoction of cinchona, with the compound tincture of cinchona, nitrate of potash, and bicarbonate of potash, being taken internally; and full doses of Dover's powder at night; lime-water or potash-water, with milk, being the beverage generally allowed.

18. As regards other lesions implicating the vagina, especially ulcers, fistulae, lacerations, or extensive ruptures, wounds, hemorrhe, polypi, tumours of various kinds, foreign bodies lodged in the vagina, prolapsus of the vagina, and cancer of the vagina (see art. Uterus, § 190. et seq.), I must refer the reader to surgical works, or to the article Vagina, by MM. Denommeaux and P. Dubois, in the second edition of the Dictionnaire de Médecine, where these lesions are very ably described.

19. II. THE VULVA is liable to diseases which are either local or constitutional. The latter requires internal or constitutional treatment chiefly, and sometimes local means also; the former seldom requires permanent benefit from local appliances, without having recourse at the same time to general or internal medication. The affections of this part, as well as of several others, are distinguished there as is made respecting those which are commonly called medical, and which are usually termed surgical; although I am obliged, by the scope and limits of this work, to observe this distinction to a considerable extent. Diseases of the vulva are of frequent occurrence at all ages and in all cases of society. They often assume serious characters, owing to concealment, neglect, or delicacy of feeling, more especially in childhood, or in early or mature age. They most frequently proceed from want of due cleanliness, from infection, from eruption and other fevers, from diseases of the uterus and appendages, and from masturbation. The purer moral states have also some influence in causing them. They may occur primarily, or consecutively; and in either case they may be simple, or complicated; with whatever disorder they may induce, or be induced by.

21. Definit. — Pain, soreness, and tenderness of the vulva, frequently with swelling, painful micturition, and more or less symptomatic fever.

22. Vulvitis may be of various grades of severity, from the slightest pruritus vulvae inflammatory irritation, to erythema, to phlegmoneous, diffusive erysipelas, and to ulcerative or gangrenous inflammations, simple or complicated. I shall briefly notice these, as well as other forms of disease of the vulva which fall under the category of inflammatory, either endemic or epidemic, and offer some remarks on these varieties of vulvitis which have fallen under my observation at the Infirmary for Children and in private practice, and commence with the slightest or least inflammatory in appearance, and proceed to the more violent and dangerous.

23. A. CATARRHAL VULVITIS.—This form of the disease is usually slight, unless it be neglected or aggravated by neglect of cleanliness. It is not infrequent in children; and in grown-up females it occurs as a form of leucorrhea, or as a symptom of disease of the neck or body of the uterus. In infants and children, it assumes a catarrhal appearance, the discharge being at first chiefly mucous, and afterwards mucous-purulent; the surface of the vulva being slightly red and swollen; but neither very irritable nor excoriated, unless neglected. It is most frequently caused by cold, by sitting on cold or damp seats, by general debility, and the irritation of ascards in the rectum, or by disorder of the digestive organs. It is sometimes a sequel of low and eruptive fevers in childhood, especially of scarlet fever; and if it be overlooked, or continue long, it may give rise, especially if aggravated by filth and an improper regimen, to one or other of the more serious forms of vulvitis about to be described.

24. B. IRRITABLE VULVITIS. — As observed in some states of the disease of the uterus, so in some affections of the vulva, the inflammatory appearances are either slight, or not very remarkable; yet the pain and tenderness are very great, or even acute. Sensibility is so morbid as not to admit of the slightest touch; and in married females sexual intercourse cannot be endured. On examination, the parts are slightly red, or rose-coloured, and covered in parts by a whitish exudation, especially about the entrance of the vagina; and it is made respecting them that swelling or fulness of the labia. The patient
VAGINA AND VULVA — Vulvitis Described. 1299

complains of a sense of heat, or lancinating pains of the parts, of smarting painful micturition, and of inability of walking. This complaint is sometimes caused by the state of the menstrual discharge, and is most frequently met with in young persons about the age of puberty, or shortly before or afterward. It frequently occurs in the catamenia, in females after marriage and during their first pregnancy, and in widows, but less frequently in these last. It is sometimes associated with one or other of the forms of hysteria, or with spinal irritation.

25. Cervical Vulvitis. — Pruritus of the vulva is often a very distressing disorder. The itching or pruritus of the parts is sometimes such as cannot be endured without resorting to friction in some way or other to allay it. There is generally a sense of heat, but seldom much pain, tenderness, or soreness of the parts, unless what may be caused by the friction resorted to. Nor is there much redness or swelling, unless such as may be referred to the same cause. But there is obviously more or less vascular erthyma of the parts, or of others in their vicinity, sometimes with increased secretion from the surface or interior of the labia and orifice of the vagina, or even a more copious discharge, owing to the frictions resorted to. This disorder is not infrequent previously to or after puberty, and often is attended by inordinate sexual desire, amounting in some instances to nymphomania, and frequently suggesting masturbation, which, although it may assuage the irritation for a time, generally tends to perpetuate or aggravate the disorder. Pruritus vulvae is also a frequent consequence of pregnancy, especially of the first pregnancy, in young puerperal habits, and sanguineous temperaments, of the discharges after parturition, and of morbid states of the catamenia. In both girls and married females, it is often caused by the state of the secretions from the follicles of the vulva and vagina, especially when they are allowed to accumulate and irritate, owing to their alteration by the oxygen of the atmosphere, the sensitive mucous and erectile tissues of these parts. It is also, at all stages of syphilis, due to worms, especially of ascariids in the rectum.

26. Eczematous Vulvitis. — An eruption of an eczematous character (see art. Eczema, § 9.) is sometimes met with on the internal or external surface of the labia vulvae, and is either dry or humid, and occasionally extends to the adjoining parts of the thighs. It generally presents a copper-coloured redness, is liable to recur at intervals, and often continues for an indefinitely prolonged time. It is attended by a sense of heat or burning, with a stinging itching. It seldom occurs in young females, but is very common after 35 or 40 years of age, and especially after the cessation of the catamenia; and in those it may continue for years, particularly in females of a full habit of body, or who are corpulent. It is not necessarily connected with any venereal infection, or with leucorrhoea, although this latter may be associated with it.

27. Erythematous Vulvitis. — The internal surfaces of the labia are not infrequently slightly swollen, diffusely red, painful and smarting, and intolerant of touch. It presents no appearance of phlebitis, is smooth or shining, the surface being hot, with a sense of more or less of painful heat. It soon becomes covered by an exudation of a whitish or ichorous lymph; and in some cases which I have seen at the Infirmary for Children, the labia have become adherent, and so firmly adherent, as to require surgical aid in separating them. This form of vulvitis is not uncommon in children, is always accompanied by that of a very full habit of body, and in these, as well as in corpulent females advanced in life, is owing to the serility of the secretions from the parts in their vicinity, to the state of the menstrual discharge, or of the lochia, and to the neglect of cleanliness. In many cases the discharges from the vagina, and cervix and ex utero, occasion or perpetuate the inflammation of the vulva. Although a comparatively slight disease, it is may be followed by more serious results; such as phelegmonous or supplicative inflammation, by inflammation of the lymphatics, or even, in rare instances, in young children, by adhesions of the labia.

28. F. Erysipelas Vulvitis. — This form of vulvitis generally resembles the erysipelatous at its commencement; but owing to the state of the secretions producing it, or the habit of the body of the patient, or to both, it is soon characterised by great swelling, and a disposition to terminate in suppuration, or suppurative, or phlegmonous, or even, in rare instances, in boys, by adhesions of the labia.

29. F. Pustular Vulvitis. — Since M. Bertonseau described inflammation of mucous surfaces with the exudation of lymph — forming a false membrane over the inflamed surface — a form of disease which he termed diaphritis — inflammation of the vulva with the formation of a false membrane — Vulvitis diaphtherique, of Erysipelatous Scientists, has been occasionally observed in circumstances similar to those which occasion this form of inflammation in the cavities of the mouth, pharynx, &c., or when this disease of the mucous surfaces is endemic or epidemic. This form of vulvitis differs from all others in the rapid formation of a false membrane on the inflamed, but very slightly swollen, surface. As it is observed in the mouth and pharynx, so it is found to extend to the adjoining canals, advancing up the vagina to the neck of the uterus, or into the urethra. This state of the disease is obviously the result of constitutional disorder, in which the circulating fluids are in some degree, although not always demonstratively, affected. It is most frequently observed in girls or young females, at certain seasons, or localities, of a cold and humid description; and the febrile disturbance attending it presents an ashen, rather than a white character. 30. H. Phlegmonous Vulvitis. — Inflammation of a phlegmonous form may commence either in the cellular tissue beneath or connecting the mucous and cutaneous structures, or in the deep-seated mucous follicles of the vulva.
or at the commencement of the vagina. It has been assigned to one or other of these seats exclusively by various pathologists; and it may very possibly originate in either, although most probably in the bladder, during the process of evacuation, or in consequence of obstruction in their ducts. This affection generally appears with heat and tension of the parts, followed by a dull and sometimes a severe pain, and affects chiefly, or more frequently, the lower half of the vulva. Pain, and a sense of tension, pressure, and fulness, extend to the perineum, and more or less febrile disturbance is developed, which may, in the course of two or three days, assume a severe inflammatory character. The bowels are confined, and the urine scanty, high-colored, and passed with pain.

The whole vulva becomes hot, and one or other of the labia is thickened and swollen, the inflammation and tumefaction extending near to the perineum. In the course of five, six, or seven days, an abscess commences in the centre of the inflamed tissues; and although it cannot be perceived externally, it may be felt by firmly grasping, between the fingers, the inner edge of the labium. A tumour, the size of an egg, or smaller, will then be found in the midst of the tumid structure; and if the abscess be at all advanced, fluctuation will be perceived by a finger of the other hand.

31. Abscess of the vulva occurs only on one side at the same time, and very rarely attacks both in succession. It is observed chiefly in young females, and especially in the recently married, and very rarely at a greater age than 40 years. M. Vellepeau met with a case in a female aged 44. I was consulted in a case of a lady who admitted her age to be 45. This distinguished physician states, that it is commonly a result of excessive coition, of disproportion between the sexual organs, or of the introduction of a foreign body into the vagina; that it may also arise from neglect of cleanliness, from irritation of any kind, whether externally and mechanically, or internally and pathologically; and it occurs in all ages. It occurs in women who have prematurely had sexual intercourse, in prostitutes, and in young females who have indulged in excessive venereal pleasures or in masturbation. It is sometimes a consequence of leukorrhea and of gonorrhoea, and of any violence or irritation to which the vulva has been subjected.

32. The course of an abscess of the vulva is generally rapid; but owing to the structure of the parts, and to the circumstance of females being aware of the cause of the complaint, medical advice is deferred as long as possible; and the history of the early symptoms and changes is not obtained until the abscess has either burst, or is ripe for opening. When left to itself, it generally bursts from the seventh to the twelfth or thirteenth day; when it has acquired a size varying from that of a nut to that of a hen’s egg. It rarely exceeds this latter size. Phlegmoneous ulcers rarely terminate in resolution, and seldom in suppuration or gangrene, and then only in cachetic habits of body. When abscesses of the vulva open spontaneously, it is generally by a perforation in the direction of the vaginal surface of the labium. In some instances more than one perforation is observed when the abscess has been large. A fistulous communication may even form, and, in rare cases, extend to the rectum, or by the side of the vagina to or around the urethra. In most cases, however, the abscess is discharged and healed in the course of a week or two. But if sexual intercourse take place during the period of incubation, the abscess may be reproduced owing to the injury or irritation of the cicatrix, and of the tender parietes of the former abscess, and to the greater susceptibility of the parts. Hence abscesses of the vulva may be reproduced several times in the same female. M. Vellepeau has seen it thus recur six, eight, or ten times in the course of a few years.

33. I. ULCE RATIVE OR ATHEMIC VULVITIS. - Nova, Phagedenische ulceration of the labia vulvae, Gangrene of the vulva, Gangrenous inflammation of the vulva. Vellepeau.—This form of vulvitis is observed chiefly in children from about the period of weaning to the ninth or tenth year of age. It was first described by Mr. Kincker Wood, and occurs chiefly in ill or insufficiently fed children, in those who live in low, unhealthy, or crowded localities or apartments; or who are the subjects of low, adynamic, or gastric forms of fever; and in any abnormal habits of body, especially in large manufacturing or other cities and towns. The disease may be preceded, as well as attended, by loss of appetite, nausea, thirst, and other febrile symptoms of an adynamic character. The pulse is quick, small, or weak; the countenance and general surface pale or sallow, and the tongue is pale and covered by a dirty-looking or clayey coating or fur. The patient first complains, locally, of painful or scalding micturition; or cries or struggles violently when voiding the urine. The labia vulvae are inflamed and enlarged, and their surfaces are of a purple, or livid-red tint, the inflammation extending over the clitoris, nymphae, and labia, and even into the urethra. A thin exudation may at this early period be observed covering these parts, which may proceed from the irritation having extended to the lower part of the vagina. Twenty-four hours hardly elapse until a number of small vesicles appear. There are 16 cases out of 20, in which it occurs in girls who have prematurely had sexual intercourse, in prostitutes, and in young females who have indulged in excessive venereal pleasures or in masturbation. It is sometimes a consequence of leukorrhea and of gonorrhea, and of any violence or irritation to which the vulva has been subjected.

34. The constitutional symptoms are now most seriously adynamic. The pulse is rapid, irritable, and compressible; the face and general surface are white or blanched; the bowels torpid and the stools offensive. The patient lies constantly on her back, with the knees bent and wide apart; and the distressing pain caused by micturition prevents her from using any effort to avoid the urine. The ulcereations vary rarely terminate in resolution, and seldom in suppuration or gangrene; and then only in cachetic habits of body. When abscesses of the vulva do not terminate in suppuration, in some cases they are foul and deep, in others they are superficial, and their bottoms present small red granulations; their surfaces varying with the severity, constitutional tendency, and the treatment of individual cases.

35. The termination of the disease also depends much upon the circumstances just now stated. When the ulceration is fully established,
the swelling of the labia minora diminishes, and the redness disappears with the extension of the ulceration, which is deep, foul, and spreading, in states of the system manifestly adynamie and cachectic, and of the circulation not only anemic, but also contaminated. The secretion from the ulcerated surface extinguishes the vitality in succession of the tissues with which it is in contact until the extension of the ulcer is arrested. As the process of destruction advances, the face becomes more blanched, the pulse remarkably rapid and small, the appetite lost, the bowels loose, the stools offensive; emaciation and anaemia being remarkable, and the discharge from the ulcerated surface most offensive; and the patient expires in the course of a few days, the duration of the disease varying much with the circumstances and treatment of individual cases.

36. If, however, this affection be seen early, and be judiciously treated, the ulcerations become clean and heal. Yet, after they heal, a yellowish discharge often continues for a considerable time from the vagina and affected parts; and causes, where due precautions are neglected, a recurrence of the malady. In most cases, owing chiefly to the extent of the constitutional disturbance—to the low grade of vitality, and to the contamination and insufficiency of the blood—the recovery of the patient is generally protracted, and is rarely of less duration than eight or nine weeks. When the ulceration is large and deep, the patient very rarely recovers, although the most decided means to arrest its progress be employed.

37. The nature and morbid relations of this most dangerous form of vulvitis are manifest from the above. It has been viewed by M. Vulpian as a gangrenous inflammation of the vulva; but the destruction of tissues quickly following the vescications on the inflamed, swollen, and livid parts, is not altogether similar to true gangrene, but rather to that of phagedenic or rapidly destructive ulceration. It resembles in most respects cancer oris, or that form of stomatitis which I have described by the name of stomatitis phlegdenanica (see Art. Stomatitis, § 24. et seq.). The causes of both maladies are the same;—they are both consequent, in rare instances, on low fevers, continued remittent, remittent of remissions, more especially on scarlet fever, and they are both arrested when admitting of this termination by the same or similar means.

38. K. Gonorhreal Vulvitis. Specific Vulvitis. This form of the disease, if not always, is generally attended by more or less irritation of the urethra. The following is nearly the description of the disease, by M. Ricard, as quoted in Mr. Actor's able work. This complaint may affect the epithelium of the mucous surface only, or the vulvar glands also, these glands, according to M. Moullier, being regarded as the organ secreting the discharge. At first symptoms are slight. There is an unusual sensation in the vulva, with a desire for sexual intercourse. This is soon followed by itching, heat, redness, and swelling. The normal moisture of the parts is much augmented; but it soon becomes increased and irritating, and aggravates the inflammation. The discharge rapidly assumes a muco-purulent state, owing to the affection of the mucous follicles. As the inflammation extends more deeply, the swelling increases; and it may then become phlegmonous (§ 30. et seq.), or be attended by oedema. If the nymph be come inflamed, they may be so enhanced as to protrude beyond the labia. Abscess may follow the swelling, or the inflammation may extend to the vulvar glands, and occasion small abscesses. Owing to the extension of the morbid action to the urethra, and to the state of parts now described, the urine is voided frequently, and produces much scanty yellow urine, which have been subject to leucorrhoea readily distingu science the discharge and other symptoms now experienced, and those to which they have been subject. With very exaggerated sensibility of the vulva, the scolding on passing urine becomes very severe, and in some cases retention of urine occurs. The inflammation may even extend along the urethra to the neck of the bladder, producing very painful and constant desire of micturition. The existence of urethritis in these cases may be ascertained, if the patient has not recently passed water, by introducing the finger into the vagina, and bringing the finger from behind forwards; if mucous pus be in the urethra, it will be at once evident. Syphilitic ulceration of the vulva is noticed under the head of Venereal Diseases.

39. L. Consequences of Vulvitis. These are, as partially noticed above, oedema, abscess, ulceration, and molecular gangrene, suppuration, extension of the inflammation to the vagina and cervix uteri, or to the urethra and neck of the bladder, or to the lymphatics and lymphatic glands. Oedema vulvæ, although sometimes caused by inflammation, is more frequently a consequence of organic disease of the heart, or of the kidneys, or of other internal organs; and it is thus generally associated with anaemia. It may also occur during the advanced stage of pregnancy, or even after parturition; in the former circumstances often rendering delivery more serious or complicated, and in the latter increasing the amount of suffering, and delaying recovery. Inflammation of the lymphatics and their glands rarely occurs in the course of vulvitis, but chiefly of the phlegmonous, ulcerative, and specific forms. It is seldom detected until pain and swelling are experienced in the inguinal glands, and then irregular streaks of remission may be perceived in the external parts, with irregular hardness or swelling of the labia, extending superficially to the groins.

40. ii. Treatment. A. The treatment of catarrhal vulvitis (§ 23.) consists chiefly of frequent ablutions with weak solutions of alum or sulphate of zinc, or with camphor-water, or sea-water, &c. If the parts present much inflammatory irritation, the local means advised for the irritable and erythematous states of the complaint may be directed, and the treatment be in other respects the same. In most cases, and especially when connected with debility, or occurring as a sequel of fevers, &c., then patient complain бу the urine only by tepid, or cold salt-water bathing; or warm salt-water hip-baths; tonics internally, chalybeates, due attention to the digestive, assimilating, and excreting functions, and change of air, &c., will be found of very great service.

41. B. Irrisurate Vulvitis (§ 24.), Pruriginous vulvitis (§ 25.), and Erythematous Vulvitis (§ 27.), are so closely allied states of inflammation, and so generally affect only the epithelial mucous surface, so that...
TREATMENT OF VULVITIS.

TREATMENT OF VULVITIS.

depletions; whilst saline aperients, and alkaline, saline, and other depurants of the blood, conjoined with tonics, are beneficial. The treatment of this variety of the disease is in most respects the same as I have advised for pseudo-membranous stomatitis (see §§ 14, 15.)

45. F. Phlegmonous vulvitis (§ 30. et seq.) may, when left to itself, especially in cachectic habits of body, occasion serious destruction of parts, sinuses and fistulous openings and communications with adjoining organs, or prolonged ulcerations. To prevent these consequences; — 1st. The patient should be kept in bed, or on a couch, in a cool temperature, with the thighs wide apart; — 2d. A considerable number of leeches should be applied between the labium and thigh, or upon the perineum; — 3d. To cover the phlegmon, twice or thrice daily, with mercurial ointment previously to applying linseed poultices; — 4th. To direct a warm bath every second day, or a hip-bath every evening or night (Veslpeau). The abscess may spontaneously open, when thus treated, from the fifth to the eighteenth day; but it is generally more beneficial to open the abscess as soon as matter is formed, than to wait for a spontaneous discharge, which may take place in an undesirable situation, or after the abscess has occasioned more or less serious alterations, such results being not uncommon in unhealthy constitutions. The question as to the situation in which artificial opening of abscess of the vulva should be made, has been decided by M. Veslpeau in favour of the external surface of the affected labium, and in the lower or posterior part of the swelling or abscess, for reasons he has assigned in the article referred to in the Bibliography.

46. G. Phagedenic ulceration of the vulva (§ 36. et seq.) is the result of a molecular loss of vitality of the tissues poisoned by the contact of the irritating and contaminating fluid into which the dead molecules are resolved. It is identical in its nature with phagedenic stomatitis, as already stated; and the local, as well as the constitutional, treatment is in every respect the same as I have advised for that serious malady. (See art. Stomatitis, §§ 31—33.)

47. H. Gonorrhœa vulvitis (§ 38.) is treated as follows by M. Ricard and Mr. Acton. In the commencement a soothing plan should be employed, and separation of the surfaces attempted, followed by lotions of nitrate of silver, in the proportion of 23 to 33 of distilled water, and by warm baths. If the inflammation has gained the deeper tissues, the soothing plan should be adopted; or leeches should be applied to the groin. If a phlegmonous condition of parts occurs, depletions should be chiefly relied on; and the moment that an abscess is formed, an opening should be made into it, in order to prevent the pus from burrowing through the cellular tissue. When urethritis is much complained of, cubets and the balsams, with demulcents, are then required. Afterwards, balsams and lotions of the solution of the nitrate of silver are required, and the remedies advised for the milder varieties of vulvitis may then be prescribed (§§ 40, 41.)

The constitutional treatment should depend upon the peculiarities and circumstances of the case. But generally this form of the disease is not benefited, but it may be injured, by vascula
morbid conditions, recollecting, however, as respects the most of them, that strict attention to ablations by suitable means; to the digestive, assimilative, depurating, and excreting functions; and to the promotion of constitutional power, and of vital resistance to the extension of disease, are the surest principles of successful dietetics.

49. III. SWELLING AND OTHER LESIONS OF THE VULVA.—These consist chiefly of hypertrophy of the nympha, of tumours of the clitoris, thronibus or effusion of blood in the labia after injuries or parturition, fistula, cancer, hermaphroditism of the vulva or of the nympha, tumours or cysts—erectile, scabious, follicular, or others—the growth of hair within the vulva, &c. These concerns the surgeon rather than the physician, and require no remarks from me. The only exception may be made in regard to hypertrophy of the nympha, which may take place to such an extent as to exclude the seat of the disease.

In unmarried females, advanced in age, this change has undoubtedly proceeded from masturbation. But in very young females, to whom this vice could not be imputed, and also in children, the nymphae are sometimes so greatly developed as to protrude far below the labia majora. Of this state of affairs I have seen several cases, one case which came before me, the very enlarged and prolonged nymphae being extirpated. The hamorrhage was very considerable, but recovery was complete. The clitoris may be enlarged as well as the nymphae; and in such cases the enlargement is probably owing to masturbation. These parts have been observed by Larrey, Gilbert, Clot-Bey, Talrich, and others, to have been the seats of elastitis; the tumours which resulted having been as large as a child's head. M. Vellapeau has referred to several cases of this nature, which, however, are not rare in Egypt and other parts of Africa.

VEINS, DISEASES.—1. This order of circulating vessels has not received that share of attention and research which it deserves in several states of disease, either implicating it more especially, or affecting the frame generally, and changing more or less not merely the blood circulating in it, but the whole mass of blood supplying all the organs and tissues of the body. Hence alterations of these vessels should not be viewed with reference to themselves only, and as local changes merely, but with a due recognition of the effects produced by them on the blood, and, through the blood, upon the whole frame. Even this apparently comprehensive view is not sufficient; it is only one aspect in which this subject should be studied—one side of the object—another presents itself to the experienced and searching eye, viz., the many various organs and the numerous local changes and structural lesions affecting primarily the several tissues and organs, frequently altering either the blood in these parts, or the veins originating in them, or even both, successively contaminating the blood and circulating systems, and ultimately altering the vital cohesion and the intimate organisation of all parts of the living body.

2. It would be impossible, even were it necessary, to consider the diseases of veins, especially in connection with those of the blood, with that amplitude which I might desire, or others expect. This subject can be viewed only in its more practical and important relations, at this place. The full consideration which I have bestowed on the several matters and topics intimately connected with diseases of the blood and circulating organs and vessels, and on the treatment of them under their respective heads has, in the early parts of the work, prevented me from attempting more at this place than to notice what has not already come under discussion.

3. It is chiefly to John VVYRT that we are A A O A.
indebted for the earliest and best information respecting diseases of the veins, and especially to the treatment most appropriate to inflammation of them. Since his time the researches and works of BAILLIE, HODGSON, CRUVELIER, MOERS, BURSCHET, DAVIS, DANCE, LEE, GENDIN, RIBES, ARNOTT, and others, have tended most essentially to advance our knowledge of these important subjects. Diseases of the veins resemble those of the lymphatics and arteries (see those articles) in some respects, and differ from them in others, particularly as regards the constitutional symptoms. The veins never exhibit an alteration in all respects similar to aneurism, because their coats yield equally to pressure, and are not subject to the forcible impetus of the blood; besides, their inner coats are more susceptible of dilatation without rupture, than those of the arteries; they are, however, more subject to inflammation and varicose dilatation than the latter vessels.

4.Osseous formations, which are so often met with in arteries, are seldom found in veins. The difference of texture is not sufficient to account for this; for, as M. ANDRAL remarks, the structures of the texture in art are precisely as that of the aorta, and the right side of the heart is organised precisely as the left; and yet ossifications are much more frequent in the aorta and left side of the heart than in the pulmonary artery and right side. The more abundant supply of ganglial nerves to the arteries than to the veins may, perhaps, tend to create a difference as to the nature and frequency of diseases of these two orders of vessels. The constitution of the blood, and peculiarities of the circulation in each, may also contribute to diversify their ailments. The circumstance of the blood being often conglutinated and organised in the veins than in the arteries may be chiefly imputed to this latter cause, and to the more frequent occurrence of inflammation in the former vessels. Pus is more commonly found in the veins than in the arteries; this is owing to three causes—1st, to the greater frequency of inflammation of veins; 2d, to the circumstance of this morbid secretion being carried into the veins by absorption; and 3d, to the probable metamorphosis or alteration of the pus-globules before they reach the arterial circulation. Perhaps the second and third causes are the most influential.

5. The constitutional effects of diseases of the veins, and the consequences of inflammation of them, differ very considerably from those which characterise the maladies of the other orders of vessels composing the vascular system; but the differences are chiefly apparent in acute inflammations of these vessels, as will be observed upon referring to what has been stated respecting these diseases.

6. I. Inflammation of Veins.—Synon. Phlebitis (from φλες, a vein); Adenentzündung, Blutaderentzündung, Germ.; Phlébite, Fr. Class.—111. Class, 1. Order (Author in Preface).

7. Definition. Tenderness, tension, acute pain, and a knotted, cord-like swelling or hardness in the course of a vein or veins, sometimes with discoloration, when the veins are superficial, extending both to, and from, the centre of circulation, with a commotio viscerarum, which often passes into an acrid or dry state, with indications of contamination of the blood, or purulent formations in the viscera or other parts.

8. The pathological anatomy of phlebitis will be more fully shown in the sequel; but it may be stated at this place that inflammation of veins occasions—1st, The formation of coagula adhering by means of the lymph exuded from the inflamed surface, to the internal membrane of the vessel; 2d, The secretion of pus, which may be surrounded by a false membrane, or by coagulated lymph, or be contained in coagula adhering to the internal surface of the vessel; 3d, The secretion of pus, which is not surrounded either by plastic lymph, or by a coagulum, but which has a free access to the current of circulation; and 4th, The secretion of an ichorous or amnion fluid from the inflamed inner membrane, which rapidly mingle with, and contaminates, the blood, and generally produces rapid and fatal changes of the structures. Instead, therefore, of viewing phlebitis, as heretofore, to consist of only two principal forms, viz., the adhesins and the suppuration, the latter being either confined or free, I would add a third, the ichorosis or poisonosis.

9. Inflammation of veins is of the greatest importance as respects both the local lesions and the consequent contamination of the blood. It is much more frequently seen than inflammation of arteries. Its seat is the cellular tissue of the vein, and the circular fibrous coat, in as far as the latter exhibits any degree of redness or vascularity; and its products are deposited in both these, and in the non-vascular or internal lining membrane extending into the canal of the vessel. It more frequently is acute than chronic, the former being distinguished by an exudation on the inner surface of the vessel. When phlebitis—inflammation of the coats of the vessel—is the primary disease, the changes of the blood, and other alterations within the inflamed vein, are consequences of this inflammation, these changes being secondary. But, when the blood in a vein is coagulated, or is otherwise remarkably altered or poisoned, it may, in such a state, irritate the internal membrane of the vein, inflame it, or all the coats of the vessel, the phlebitis being thus consecutive or secondary. The disease may be seated in a single vein, or extended to several, or even to many, whether it be thus primary or consecutive.

10. John Hunter first demonstrated the pathological changes and the consecutive phenomena of phlebitis. Many years afterwards, SANE, B. TRAVERS, AMBERTH, HODGSON, and BURSCHET, directed their attention to this disease; and more recently RIBES, ARNOTT, DANCE, DAVIS, R. LEE, MARECHAL, BOUILLAUD, CRUVELIER, VELPEAU, BLANDIN, ROJITANSKY, and others, have contributed facts and opinions respecting it. Nevertheless the subject is by no means exhausted; for there still remain various topics connected with it, both pathologically and therapeutically, requiring further elucidation and confirmation.

11. The causes of Phlebitis.—Inflammations of the veins are much more frequent in the male than in the female sex, if phlebitis consequent upon parturition be excluded from the account, and in ages from fifteen to fifty. This greater frequency in males, and in the adult periods of life, is probably owing to a greater ex-
posure to injuries and other exciting causes in this sex and age. These causes are numerous, but they chiefly consist of external injuries of various kinds, more especially punctures, lacerations, abrasions, fractures, and contusions; punctures or divisions of veins, particularly with blunt, ragged, foul or infected instruments; punctures or injuries in anatomical dissections or during post-mortem inspections; cuts or scratches when preparing or dressing animal food, especially game, &c.; operations, &c., when performed in foul wards of hospitals, or in low, impure, and ill-ventilated localities or apartments; fractures, compound or comminuted, in similar circumstances; ligatures or surgical operations on veins; the application of caustics or local irritants; the existence of ulcerated or tubercular cavities, or of abscesses or malignant formations, with which veins communicate, or into which either of these morbid matters pass; and the imbibition of morbid matters by veins or sinuses, from cavities in which morbid secretions, fluids, or deposits accumulate, as the cavities of the uterus and cervix uteri, or from ulcerated cavities in the lungs, liver, &c., or from necrosed bones, or sphecatelated structures, or from purulent matter lodged under the flaps formed in amputations. These last, venesections, and puncture or other wounds, are the most common exciting causes of phlebitis.

12. In hospitals, especially during the prevalence of hospital gangrene or erysipelas, either within them or in their vicinity; in camps or barracks, prisons or crowded vessels, especially transports; and in low, damp, crowded, and imperfectly ventilated situations, and in localities exposed to noxious exhalations, particularly in malignant states of the air, or when erysipelas is prevalent in them, and when the more common exciting causes are of frequent occurrence, phlebitis may then assume an endemic or epidemic prevalence. In these circumstances and seasons, venesection and other operations involving veins, can seldom be performed without the risk of producing the atheric, or most dangerous form of phlebitis (§ 21. et seq.); and indeed these operations, should be on such occasions avoided as much as possible.

13. Phlebitis is sometimes not only caused by, but often also associated with, organic lesions of internal organs, especially with ulcerations of the intestines, with abscesses in the liver, kidneys, lungs, brain, ears, &c.; and is occasionally detected in the mesenteric, the portal, and the pulmonary veins, and even in the veins and sinuses within the cranial, upon dissection. It is, however, most frequently associated with uterine diseases, and with inflammations and abscesses of the uterine ligaments; the plague, scrofula, and other diseases, having become consecutively inflamed, as stated in the articles on diseases of the Perinatal States, and of the Uterus.

14. ii. Symptoms. A. The symptoms of athenic phlebitis may be divided into two stages, namely, — 1st. Those which are local, and characteristic of the malady; — 2d. Those which indicate the contamination of the blood, and general infection of the frame. — 1st. The local signs are generally very manifest when any of the more superficial veins are attacked; but they are very equivocal when the deep-seated and internal veins are implicated.

Phlebitis usually commences with sharp or severe, sometimes violent, pain in a part, or in the course of a vein. If the vessel be superficial, it will be found hard, tense, as if stretched, forming under the skin a cylindrical or knotted cord. At the same time the skin sometimes presents a reddish or more extensive erythematous blush, or even an erysipelas-like appearance. If the vessel is more deeply seated, tension and hardness may be felt in the situation or course of the pain. Congestion or engorgement of the capillaries of the cellular tissue adjoining or surrounding the inflamed vein, are afterwards observed; and if several veins, or a large trunk is affected, this tissue, and the parts below or distal to the seat of disease, become edematous, or very remarkably swollen. With the local lesion, the constitution sympathizes more or less remarkably, the general symptoms varying with the severity and extent of the inflammation, and with the temperament and habit of body of the patient; but quickness of pulse, heat of skin, headache, loss of appetite, thirst, and impaired secretion and excretion, with other symptoms of inflammatory fever, are commonly observed.

15. In favourable states of the constitution, and when judiciously and early treated, the disease may not proceed further. The coagulum formed in the inflamed veins adheres to the varieties of their canals; a collateral circulation is established, and the inflamed veins no longer permit the circulation of blood through them. In some cases the inflammatory exudation on the internal surface of the vessel, or the coagula formed on its sides by means of this exudation, leave a central canal, allowing a partial circulation of blood along it. In other instances the inflamed veins secrete pus, which may be so abundant as to give rise to fluctuation, or other indications of its presence in the sub-cutaneous chord, which is felt when the vein is superficial; and, if an artificial issue is not given to it, the matter makes its way into the adjoining cellular tissue, and forms an abscess, which follows the usual course. When the local lesion is severe, it does not terminate in either of these ways; and when the morbid exudation, or purulent matter furnished by the inflamed vessel, is carried into the blood, the system becomes generally infected, owing to the contamination of the blood thus produced, and the second period or stage of the malady is developed — or the state of pneumonia.

16. 2d. This stage of phlebitis, or that of vascular infection, may take place rapidly, or not until after a few days, the rapidity of its occurrence depending upon the nature of the exciting cause and the constitution of the patient. It usually commences with chills or rigors, followed by hot skin, and other symptoms of fever, and by perspiration. These paroxysms of chills, fever, and sweats generally return at irregular intervals, assuming a remitting form; but in some instances they are periodic. With these exacerbations, anxiety, lassitude, distress, or slight or occasional wandering delirium appear; and these are followed by more continued delirium, which is generally low or muttering, rarely lively or excited. The tongue, previously farred, now becomes dry or encrusted, is trembling, or imperfectly protruded; the teeth and lips are fuliginous; the countenance is wan.
VEINS—Inflammation of, Described.

dusky or pale, and lurid, and the symptoms assume a typhoid or adynamic character. The pulse is small, very frequent, and soft. These phenomena are observed in nearly all the cases at this stage; and others are less constantly present, especially restlessness and vomiting; diaphoresis, that is, perspiration, and the urine turbid and foetid or ammoniacal, and the surface dark or dusky, or slightly jaundiced.

17. During this stage, and often at an early period of it, secondary abscesses form in some internal organs, with indications of oppression, ten- derness, or distress, referred especially to the region in which the affected organ is seated. In some cases the larger joints become extremely painful and swollen, from the formation of pus within their capsules. Purulent deposits, without any very manifest indication of pre-existing inflammation, sometimes form not only in the internal viscera, or in the joints, but also in the subcutaneous tissues, and even in the brain, occasioning profound coma. If this stage continue even for a few days, extensive bed-sores and sphacelations occur in the situations on which the weight of the body chiefly rests; and, the sensibility of the skin being in great measure lost, the urine becomes ammoniacal, or the functions of the kidneys much impared, contamination of the circulation is further increased, and its consequences accelerated, death generally ensuing with a celerity according to the extent and rapidity of these changes.

18. The extention of the inflammation is generally in the direction of the heart, or of the current of circulation; but a fatal result often takes places before the inflammation reaches the vena cava, or even the larger venous trunks, owing to contamination of the blood by the exudation, or purulent matter, from the inflamed parts. In some cases, however, the disease pursues a different course, and extends to the smaller ramifications. Mr. Abernethy met with a case of phlebitis after bloodletting at the bend of the arm, in which the veins were affected down to the hand. This case was observed occasioned by the complete obstruction of the part of the vein first affected by a coagulum or exudation of lymph. It may also be partly the result of the state of constitutional power. It is not in frequent in purerphal phlebitis, the cause of which is chiefly the inhibition of banious matters from the internal surface of the uterus, aided by shock and vital depression, and by the predisposition produced by an impure air.

19. iii. Of the different pathological conditions observed in phlebitis.—The several pathological states constituting the different varieties of inflammation of veins have not been sufficiently investigated and demonstrated by pathologists; and most writers have described two varieties only, namely, 1st, the adhesions or common, —and 2d, the sphacelations, and, whilst they have viewed the former as merely a local disease, they have considered the latter as productive of vascular contamination and general infection. —a. Of these varieties it may, however, be remarked, that, although the adhesions is characterised chiefly by an exudation of lymph more or less adhesive and concrete, on the internal surface of the inflamed vein, and often no further affecting the blood than causing the formation of a clot within or near the inflamed part, yet it is attended by more or less sympathetic febrile disturbance; and that the coagulum thus formed may be productive of much continuous disease of the vein, if the local and constitutional treatment be not judiciously managed. Even after the excitation of lymph, or the formation of a coagulum, by means of which the extension of the inflammation and contamination of the blood are prevented, if constitutional power and vital resistance be much reduced, the coagulum thus formed may irritate the internal surface of the vessel, and either perpetuate or re-kindle the inflammatory action.

20. b. The suppurative variety of phlebitis is generally productive of contamination of the blood and of most dangerous constitutional disease. Nevertheless instances are occasionally observed, in which the purulent matter at first formed, mingling with the blood in the vessel, causes its coagulation, and the coagulum thus formed restrains the circulation and the extension of the inflammation in the direction of the heart, and either allows the morbid action to subside, or favors the extension of it to the more external coats of the vessel and to the surrounding cellular tissue, occuring being in great measure lost, the urine becomes ammoniacal, or the functions of the kidneys much impaired, contamination of the circulation is further increased, and its consequences accelerated, death generally ensuing with a celerity according to the extent and rapidity of these changes.

21. c. Authentic, or diffusive, or poisoned phlebitis, has not hitherto been described as a very important variety, although it is the most dangerous of any form which the disease assumes. It occurs in all the circumstances, and arises from all the causes, which occasion the other forms of phlebitis. But it more especially proceeds from causes superadded to these, more especially from those which depress the vital energies, and infect the system. It is generally the result of two classes of causes, either a constitutional derangement or a failure of the constitutional powers, and produces more or less of general cachexia before the vein is injured or wounded,—and 2d, those which lower or exhaust the energy of the body, and either prevent the depuration, or favour the contamination of the blood during or after the infection of the injury or the other exciting causes of the phlebitis. The first class comprises malaria of all kinds; the foul air of crowded wards; or that produced from the discharges or exu- dations of the sick or of others; improper or insufficient food, &c.; the second includes those already mentioned, when they come into operation directly and after the infliction of the injury, or subsequently to the other exciting causes of the disease, violent shocks to the vitality of the frame, poisoned wounds, abrasions, &c., infectious emanations from erysipelas or gangrenous sores, or morbid discharges; the absorption of purulent, putrid, or oncidial excretions from sphacelated, necrosed, or otherwise altered structures, or of decomposed blood, or vitiated secretions and excretions.

22. (a) This variety of phlebitis is characterised by the rapidity, severity, and the fatal tendency of the local and constitutional symptoms, and the marked depression of vital power, and the sus-
tamination of the circulating fluids, by which they are attended. Organic nervous energy is remarkable higher than in the acute states, situations of life frustrated, and more or less lowered. The functions of the brain are early disturbed, and the pulse becomes rapid, soft, open, and compressible; the surface of the body soon losing its vital appearance, and becoming livid, dusky, and sallow, sometimes dry and harsh, and ultimately clammy and cold. Delirium or delirious excitement occurs in almost every instance. Locally, edema, cellular infiltration, great tenderness on pressure, boggy swellings, and diminished heat on the affected limb, are often remarked; and if the injured or affected vein be exposed, as when the disease follows venesection in the circumstances just alluded to, the wound is gaping, union of the divided tissues not having taken place, and an ichorous or a serous fluid exudes from the part, or slight hemorrhage occurs on examination. In addition to the above more constant phenomena, others are observed, arising out of the varying combination of the predisposing and exciting causes, and the state of the patient. These are chiefly a tympanic state of the abdomen, retching or vomiting, diarrhœa, the evacuations being offensive and unnatural; the rapid occurrence of bed-sores; offensive or ammoniacal states of the urine, severe pains and swellings in the joints or extremities; congestions or purulent infusions of internal viscera, with tenderness and oppression referred to the regions corresponding with the affected organ, &c.

23. When uterine phlebitis takes place, it may assume either of the forms above described, and owing to such forms, and to the circumstances in which they severally appear, the different varieties of puerperal fever are developed; the more malignant kinds of these fevers being the results of the ichorous and serous fluids imbibed from the interior of the uterus by the uterine sinuses and veins, or of the morbid exudation from the mechanically inflamed veins of the uterus and its appendages, and of the consequent contamination of the blood, aided by the vital shock of parturition, and by the fear or infectious air in crowded or ill-ventilated lying-in hospitals or wards. (See Art. Puerperal Diseases.)

The appearances observed in dissection of fatal cases of phlebitis, as respects the veins, are described in the sequel (§ 57. et seq.); those which regard the frame generally, are fully given under the head Puerperal Diseases (§ 221. et seq.), and are nearly the same as those observed under postpartum dynamite fever (§ 510. et seq.); and those which are found when phlebitis occurs contumaceous and diffusive abscess, are described in the article Abscess (§ 27. et seq.).

* In the following case, by M. Lebras, as quoted by Mr. Arnett, some of the most remarkable secondary effects of phlebitis are described. "Gasper Golderger, subject for the last six weeks to epilepsy, was blest twice on the arm on the 1st of November, 1866; on the 8th, from the foot; and on the 15th and 18th, from the jugular which is in the neck. The part from the arm (the right), which on the following day felt painful; somnolence and tension were observed round the aperture: 15th, arm very painful and swollen from the shoulder to below the elbow; edges of the puncture, red; this condition continued, and some yellowish color; pulse feeble and frequent; 16th and 19th, fever more indicated, tongue, dry and atonic, great pain in the arm; 21st and 25th, lies supine; prostration of strength; heat of skin; tongue, dry; pain in the right side of the chest; respiration, short; 23rd, tension of the arm diminished; some pus flowed from the wound made in bleeding; respiration short. Died at night, seven days after the receipt of the wound in the arm."

In this case the wound in the cephalic, open; the vein filled with pus through the whole length, i.e. from where it terminates in the axillary to the head of the elbow, where it divides into the median cephalic and superficial radial; the latter of which contained pus for two inches below its origin. The contents of the arm, a quantity much thickened, indurated, and red. In the intercarpal column of the pectoral muscle of the right side".
been recorded. The disease may also extend along the veins below the seat of injury, especially when the circulation in the vein is obstructed by lymph, coagula, etc. Phlebitis in this situation may present either of the forms described above.

28. (b) The veins of the lower extremities, and the iliac veins, or either separately, may be inflamed; the former from the same causes as occasion phlebitis in the arm, the latter most frequently as a consequence of the puerperal state, or of the cancer of the uterus, and of tubercular disease. Inflammation of the iliac veins is most frequently manifested in the form of phlegmon alba dolens (see this Art.), although phlebitis is not the only pathological lesion of this disease. M. Toumouche contends that the much more frequent occurrence of the malady in the left thigh than in the right, is owing to the accumulation of masses in the sigmoid flexure of the colon, and to the consequent pressure made on the iliac vein, to the retardation of the circulation through it, and to coagulation of blood in it. (Gaz. Méd. Avril, 1844.)

29. (c) Inflammation of the vena porta has been observed by M.M. Rines, Bouillaud, Dance, and Pierre, and they, as well as others, have ascribed redness of the internal surface of the ramifications of the vena porta, and of the hepatic veins, to inflammation; but it is not improbable that this appearance is more frequently owing to caldarium incrustation of the lining mater of the blood. True inflammation of the vena porta is a very rare occurrence; it is attended by a sense of weight and of pain in the right hypochondrium, greatly increased on pressure; by regular or irregular rigors; by extension of pain to the right shoulder; by jaundice, more or less developed; by nausea, vomitings, and sometimes singultus; by diarrhoea, more or less bilious, and ultimately by the usual indications of paroxysmal infection of the blood. These symptoms are, however, in most respects, the same as those accompanying acute abscess of the liver.

30. (d) The sinuses of the dura mater are not infrequently inflamed, consecutively on injuries to the brain, membranes, and substance of the brain, on inflammation of these parts, on inflammation of the car, on cancers of the temporal or other bones of the cranium. They may also become inflamed in the advanced course of erysipelas of the scalp, and of other maligns and lesions, as I have fully described many years since. (See ATL. BRAIN, Sect. Inflammations of Sinuses of the Dura Mater, and of the Vessels of the Brain, § 37. et seq., vol. i. p. 208. 9.)

31. (e) The umbilical vein has been found inflamed in recently born children, by M.M. Sasse, Breslau, Dupleau, and me; and has been referred to ligature of the chord. It has been observed associated with erysipelas, with peritonitis, and with enteritis. The veins of bones have also been noticed by M. Gerdy. Uterine phlebitis has been considered in the Article on Phlebitis uteri or Ille (See ATL. DURE, § 197.)

32. (f) Inflammation of the vena cava is met with only consecutively upon inflammation of the uterine iliac or other veins. M. Bérard has found inflammation of the vena cava extending as high as the confluence of the venous veins in cases of phlebitis dolens: cases of inflammation of the cava have been observed and described by Travers, Hodgson, Dance, and others. The symptoms indicating extension of inflammation and of its consequences to this vessel are rather inferential than positive. These consequences are the exudation of lymph, the formation of pus, or of coagula, or of all these, and more or less obstruction of the circulation along the vena cava. If there be observed, consecutively upon phlebitis of either lower extremity, acute or rapidly developed edema, or dropsy of both the extremities, especially during the puerperal state, or at an advanced stage of fever, or at an early period after the subsidence of fever; and if, after the occurrence of edema of both extremities, indications of the development, in the surface of the trunk, of a supplemental venous circulation, it may be inferred with much probability that inflammation and its consequences have extended to the vena cava.

33. Obliterazione has been observed by Haller, Wilson, Bailly, Cline, Reynaud, the writers already named, and by others, to follow inflammation and obstruction of the vena cava. The cases which have been recorded of this remarkable lesion have presented extensive anastomoses, not only between deep-seated veins, but also between the principal superficial veins of the trunk, these latter appearing uncommonly enlarged, and anastomosing with each other. This very great development and free anastomoses of the superficial veins of the trunk have followed gradually upon the dropical or edematous state of both extremities; but, in some cases, especially those under consideration, and of most marked enlargement and anastomoses of the superficial veins, the edematous state of the lower extremities gradually diminishes. The particular veins by which the supplemental circulation is carried on are in some respects different in different cases, according to the seat of obstruction or obliteration of the cava, and to the trunks of veins, from which the inflammation extended.

34. VII. THE DIAGNOSIS. — Phlebitis may be mistaken, at an early period of its course, for lymphangitis, or lameness may be mistaken for the former. But the large cylindrical channels are manifesting in diverse forms, appearing when the superficial veins are inflamed, and the cedema of the distal or more remote parts, cannot be readily mistaken for the redness, painful, small, straight, and knotted lines passing in the direction of, and enlarging, the lymphatic glands, above the seat of the complaint. In neuritis and neuralgia the pain is more acute or purgant than in phlebitis, and the appearances observed in phlebitis are not present, especially the cedema of the parts below the seat of pain, etc. When the consequent or contaminating effects of phlebitis supervene, the hot fever, the dusky, sallow, and discoloured skin, the diarrhoea, the rapid weak pulse, delirium, etc., although assuming the form of a dynamic fever, may be distinguished from this latter by the antecedent local symptoms, by the causes, and by the whole history of § 189—197.)

35. VIII. THE PHILONESS. — The danger of phlebitis is always considerable, because, although it is by no means imminent as long as the disease is merely local, yet infection and contamination of the blood, on which great danger depends, may unexpectedly and suddenly supervene. The symptoms
described above (§ 16, et seq.), as indicating this contamination of the blood, and more especially those which attend consecutive or diffuse abscesses in the lungs, liver, or other organs, are always those of extreme danger. Cases presenting signs of internal consecutive abscesses are irremediable.

37. II. Treatment of Phlebitis. — The concluding one of the above inferences will indicate the principles which, in my opinion, should guide our practice in phlebitis. The following circumstance may have had some influence in directing my attention and influencing my views regarding this important subject. When I was in London, a short time, in August 1815, I had occasion to converse with a well known public man of that time, who informed me that he had been, about thirty-five years previously, a patient of John Hunter, he having suffered an attack of inflammation of the veins after venesection, which had been twice repeated, to a large amount, for pneumonia; and that the inflammation supervened on the last blood-letting. But it was not only the occurrence of the phlebitis after the last depletion which made the impression on my mind, but chiefly the treatment which he informed me had been prescribed by John Hunter in his case. This consisted, as he stated, of preparations of bark conjoined with other medicines, and of a very liberal allowance of port wine — upwards of a bottle daily — until he recovered. This treatment was altogether so different from what was generally taught in lectures and textbooks, that I continued to reflect upon it, and to contrast it with the means of cure, which I afterwards saw adopted on the Continent and in this country, for this disease, and which are still recommended in surgical and medical works. When it is considered that a very large proportion of the diseases of the puerperal state, and most of the fatal cases of amputation, proceed from inflammation of veins, and from the imbibition of purulent or sanguineous matters by the veins into the blood, infaming the veins and contaminating the circulating fluids, or in other words, producing effects to which the term pyemia has recently been applied, but with little regard to pathological accuracy, the importance of determining the true intentions and principles of cure for this malady must be apparent.

Upon what rational grounds can we advise, as very generally advised, large local and general depletions, and a strict antiphlogistic regimen for a disease which is frequently a consequence of such depletions and regimen? Upon what therapeutical principles can means be recommended for the prevention or cure of phlebitis that tend to promote the imbibition, or absorption, and the circulation of morbid or poisonous fluids in the blood, to prevent the formation of a healthy lymph whereby the extension of the disease may be arrested, and to prostrate the vital resistance opposed by the constitution to the contamination, not only of the blood, but also of the soft solids? — and to the production of all these effects the means usually advised for phlebitis cases of phlebitis in France and Germany during 1813 and 1816, and during 1819 and 1820; and, after considering the treatment which was there generally adopted. These inferences, as well as the treatment which I have recommended in consonance with them, have always been given in my lectures on Practical Medicine, from 1833 until 1843, when I ceased to lecture.

* * * Les premiers accidents inflammatoires que l'on observe sur le trajet d'une veine seront immédiatement combattus par les antiphlogistiques les plus actifs et les plus efficaces: Salgus; applications de sanguis en grand nombre, et plus ou moins répétées, suivi du conseil de force des sels, fomentations émollientes, tels sont les moyens qu'il convient de mettre d'abord en usage." (Art. Veins, Inflammation, in Dicr. de Méde, 31 ed.)
most certainly tend. With what rational intention are means prescribed to arrest the extension of inflammation of the veins and the contamination of the blood that actually and incontrovertibly favours both the cure of the disease and the prevention of a certain tendency to accelerate, if not to cause, a fatal issue than the natural course of the disease itself? The operation of the means of cure in this disease require to be studied and ascertained with as great care as should be devoted to the pathological changes and the consecutive alterations which constitute the nature, and occasion the imminent danger of the malady. An empirical treatment of phlebitis more frequently increases than diminishes the danger; and such empiricism, whether in phlebitis or in any other disease, being the result of ignorance, increases the number of fatal cases, and generates and perpetuates in the mind of the practitioner who is thus imperfectly informed, a scepticism in which he takes refuge, and under which he attempts to conceal his ignorance and to debase his vocation. The sceptic in medicine is ignorant not only of the nature and principles of a morbid phenomenon, but also of the operation of remedial agents. He is incapable of forming rational views, and is quite impotent as to their accomplishment. He therefore deems what he feels himself incapable of performing, and instead of relinquishing his efforts, he endeavours to impede his failures to the imperfections, if not to the total inefficiency, of the science; and by continuing his practice, and by thereby perpetuating his wants of success, he persists in furnishing evidence, not only of his own incompetency, but also of the insincerity of his professions; he at once admits that he practices a lie; that he professes to perform what he has no hopes of performing; that he may delude, but that he cannot cure. But, leaving the medical sceptic to luxurate in his practice and in his belief, and advising him to reconcile the former with the latter, if this be possible in any other way than by relinquishing the one in favour of the other, I proceed to consider the indications and means of treating phlebitis, which extensive opportunities of observation disclosed; opportunities, however, in which I was then an observer only, not an actor, and which furnished me more numerous proofs of a practice which ought to have been carefully avoided, than evidence of any resulting benefit.

38. I. A View of the Treatment which has been advised for phlebitis may, not without some advantages, precede the consideration of the means which I have long believed to be the most appropriate to this malady. Former writers have generally advised very opposite means for the different stages of the disease, for the local affection, and for the general infection of the frame consequent upon it. Thus we find in one of the ablest treatises on diseases of veins (in Diet. de Méd., 2d ed.) which have recently appeared, it is recommended to employ ablatio with diaphoretic, to the application of leeches in great numbers, and more or less frequently repeated according to the strength of the patient; to emollient fomentations; to refrigerants; to the application of ice, or to cold emulsion to the seat of inflammation; in the first period of the disease; and, in order to second the effects of this rigidly antiphlogistic treatment, the application of large quantities of mercurial ointment so as to rapidly affect the salivary glands.

39. M. Pasquier and others have had recourse to the application of narcotics locally, if the form of that have a certain tendency to accelerate, if not to cause, a fatal issue than the natural course of the disease itself? The application of quantities of opium, or to similar applications, placed along the course of the inflamed veins, and frequently renewed, so as to be always wet. M. Bonnet, of Lyons, has had recourse to a very opposite treatment; viz., to the application of the actual cautery to the part where the vein is wounded, in order to prevent the absorption of pus from the inflamed vein. But the cases which he has adduced in support of his practice are too few and inconclusive to found upon them a novel a plan of cure.

40. The local treatment advised by John Hunter, and advocated by Bennet, Ray, Velpeau, and others, had for its object to prevent the extension of the inflammation towards the heart, by enabling the constitution to throw out coagulable lymph at the inflamed part, by means of which the blood might be coagulated, or the vein obstructed; the morbid phenomenon of the vein above the seat of inflammation was likewise advised with this intention. These measures often were successful, but they often also failed. The remedies prescribed, however, with this view, were not always appropriate to the period of the disease, or to the constitution and habit of body of the patient, and were often resorted to at a too advanced stage, when the blood had already become contaminated, and when means calculated to neutralize or to counteract the contamination, and to depurate the blood, were required. M. Breuer attacked this very rational indication, or method, of arresting the extension of the inflammation, by contending that it was most difficult to obtain an adhesive form of phlebitis by medical treatment. But the supporters of John Hunter's doctrine had more extended views than the mere development of the adhesive form of the disease by enabling the constitution to throw out coagulable lymph. They viewed, or at least hoped, that the lymph effused would favour the coagulation of blood in the inflamed veins, whereby the circulation in these veins would be entirely obstructed, and the extension of the inflammation, as well as the contamination of the blood, would be either delayed or prevented, as they also knew that the best means of limiting inflammation is any surface, more especially in that of circulating vessels, were those which supported oor developed constitutional power and vital resistance to the impression of injurious agents.

41. If the views as to the treatment of the local stage or changes in phlebitis were thus diverse, those proposed for the second stage, or that of vascular infection and contamination, were no less so. The young pathologists of Paris in this matter displayed their acumen in ingenuity; but beyond this quality no further praise can be awarded to general blood letting, the application of leeches in great numbers, and more or less frequently repeated according to the strength of the patient; to emollient fomentations; to refrigerants; to the application of ice, or to cold emulsion to the seat of inflammation; in the first period of the disease; and, in order to second the effects of this rigidly antiphlogistic treatment, the application of large quantities of mercurial ointment so as to rapidly affect the salivary glands.
proportion in the blood which was left in the body. The fate of those who were thus treated may be readily predicted. Then was proposed the opposite system; namely, to engorge the patient with diuretics, by means of which the poisonous materials may be diluted, their action rendered less injurious, and their elimination promoted by means of the skin and kidneys. M. PERRY, the apostle of this doctrine, in his mémoire on "problème," or purpura, added some evidence in its support. The due promotion of all the depurating functions, not only those now named, but also those of the intestines and liver, by suitable means, and by appropriate combinations, are important remedies for the second stage of this malady, but in most cases more even than these are required.

42. Some writers have supposed that the morbid materials which have passed into the blood may be neutralised by disinfectant or similar agents, such as the chlorides; and in certain forms they may be of service, and may with some reason be resorted to. But upon what rational grounds can repeated emetics, or antimonials, or mercurials be advised, unless upon the pure empiricism which is based on impetus, but very doubtful success? Other writers have been more likely to stress the extraction of vital power, and its consequences, in the second stage of phlebitis, and have had recourse to tonics, especially to the preparations of cinchona, to wine, and various restoratives. The propriety of the practice cannot be doubted, especially if adopted at a sufficiently early period, and if conjoined with means appropriate to existing pathological states and to the circumstances of individual cases.

43. Treatment advised by the Author.—A question, preliminary to entertaining the subject of treating phlebitis, suggests itself, namely, Is there any plane by which the disease may be prevented? Phlebitis is most frequently a consequence of amputations and similar operations, and of operations on the veins themselves. Of these latter venesection is the most common efficient cause. From long and diversified observation I am convinced that, when phlebitis follows venesection, this operation ought not to have been performed, the states of the constitution and of the circulation actually not requiring it; and that this has more especially been the case when it has been repeated more than once, or when the vascular depletion has been carried too far. Most of the fatal cases of amputation result from phlebitis and its consequences. Now, what are the circumstances which favour the occurrence of phlebitis after amputations? These are chiefly, 1st, The shock given to the constitution by the operation; 2d, The anæmised state of the system, and the exhaustion of vital power in many cases at the time when the operation is performed; 3d, The collection of purulent matter under the flaps, and bathing the surface of the stump, and the mouths of divided veins; 4th, The state of the atmosphere in hospitals, wards, and places in which the operation is performed and the patient is confined. 5th, The loss of constitutional power may be promoted, and vital resistance to the invasion and extension of phlebitis be upheld, must depend upon the circumstances of individual cases and the acumen and experience of the physician.

44. (a) The shock produced by the operation, especially when great or prolonged, is not only the result of reduced vital power, but also the cause of coagulation of blood in the veins and of the injurious action of the coagulated blood on the coats of the vein (see Art. Strokes). Hence the more severe and prolonged the shock the more likely are these effects to be produced.

(b) Many cases require amputation, under unfavourable circumstances, and in others it is so long delayed, owing to the fears of the patient, until these circumstances are developed. When the constitutional power and vital resistance of the patient to disease are reduced, and the blood altered by impaired nutrition and imperfect coagulation—which, when organic nervous energy is depressed, and the blood diminished in quantity, in crisis, or in red globules, or impaired in quality—then a predisposition to phlebitis, when the veins are implicated in surgical operations, is thereby produced.

46. (c) The collection of purulent matter under the flaps, often favoured by the union of the integuments, acts most injuriously upon the internal coats of the veins; and it may even be partially absorbed by the mouths of the veins in the surface of the stump, thereby producing pyaemia and its usual results. These effects are other writers have been more likely to stress the extraction of vital power, and its consequences, in the second stage of phlebitis, and have had recourse to tonics, especially to the preparations of cinchona, to wine, and various restoratives. The propriety of the practice cannot be doubted, especially if adopted at a sufficiently early period, and if conjoined with means appropriate to existing pathological states and to the circumstances of individual cases.

47. (d) The injurious influence of a foul air in cases where veins are implicated in surgical operations is sufficiently manifest; and the frequency of phlebitis and pyaemia in hospitals, both civil and military, from this cause, is often greater than is supposed. I witnessed this influence and its effects in numerous instances soon after the Peace of 1815, both in France and Germany; and, in many more, neither the cause nor the effect was recognised. The treatment also in these circumstances, and immediately after operations implicating veins, was often injurious and calculated to occasion the mischief which it was intended to prevent. At the period now alluded to, notwithstanding the wide use of leeches, phlebitis and its consequences were but imperfectly understood. It was not until a few more years had elapsed that the pathology of the disease was fully investigated, and up to a very recent period, and even to the present time, neither the prevention nor the treatment of phlebitis has been satisfactorily illustrated. It has been a much too general practice to have recourse to a too strictly antiphlogistic treatment and regimen after amputations, thereby aiding other causes in producing phlebitis and pyaemia. The extent to which such treatment, however, should be carried, or how far its opposite should be adapted, as well as the means by which constitutional power may be promoted, and vital resistance to the invasion and extension of phlebitis be upheld, must depend upon the circumstances of individual cases and the acumen and experience of the physician.

48. (e) The means used to produce anaesthesia during surgical operations, not improbably may favour the occurrence of phlebitis and pyaemia. This topic requires careful examination. A recourse to those means has its advantages and disadvantages. The former are, the greater readiness of the patient to submit to an operation at a time when it is most likely to be successful, and the
feeling in the mind of the surgeon that he is not inflicting suffering. The latter are, the depressing influence of anesthetics on vital power, the extinction of that amount of pain in operations, which tends to protract, and develop a salutary reaction and to favour the prevention of injurious changes after the operation; and, more especially, the alterations produced in the constitution of the blood by the passage of the anesthetic vapour into it. These disadvantages were so great to me on several occasions immediately after the discovery of the means of producing complete anesthesia, and subsequent observation has confirmed my opinion respecting them.

49. From the above it will be inferred, that the avoidance, as far as may be, of the several circumstances which favour the production of phlebitis, is of great importance; that all operations implicating veins should be performed in a healthy state of the system as may be possible; that vital power and resistance should be supported and not depressed; that all contaminating influences should be avoided, and that the healthy constitution of the blood ought to be studied before and after such operations, and nothing done to alter it; and that the confidence of the patient in a successful result should be upheld, and roused or increased when depressed. Conformably with these propositions, it will be manifest, that a pure, dry, and temperate atmosphere; perfect repose of a limb or a part in which a vein has been injured or wounded; protection of a wound in a vein from the access of the atmosphere; and a healthy discharge of the digestive and depurating functions, and physical and mental quietude, are amongst the most essential means of preventing phlebitis, and of counteracting or neutralizing many of its causes.

50. Treatment of the First or Local Period of Phlebitis.—This should vary with the causes of the inflammation, with the symptoms complained of, with the habit of body of the patient, with the presumed extent to which the disease has advanced, and with the situation of the inflamed vein. The causes and seat of the inflammation equally forbid general dejection; and, unless in very plethoric or robust subjects, even local depletions are seldom required. Pain and tenderness are rarely removed by them, even in these subjects, and never in persons otherwise circumstanced. Fomentations, especially those usually applied, sometimes assuage the pain, but they favour the extension of the inflammation along the vein, and prevent or diminish the chance of procuring the occlusion of the vein by the production of coagulable lymph in the inflamed part. The chief objects, as to the local affection, are, to diminish inflammation and its usual products in the part; to render these products as little injurious as possible by causing occlusion of the vein, and, by these means, to prevent the contamination of the blood and the supervision of the second stage of the disease by the usual exudations which take place into an inflamed vein. The means which are most to be depended upon for the fulfilment of these intentions are generally those which also remove the more distressing local symptoms; and, whilst they tend to promote an operation of the three objects now proposed. The local as well as the constitutional means may be varied to meet the exigencies of particular cases, and the circumstances just alluded to; but even whilst the disease is still local, internal remedies should be promptly and properly prescribed, as protracted, tends sligly. These latter have been, for the cases which have come under my care since the commencement of my practice, either one or other of the limenitcs prescribed in the Appendix (see Form. 295, 296, 297. 300. 307. 311.) applied in the form of an embrocation over the seat of the phlebitis, by means of two or three falls of flannel or of sponge-puline; or an epithem of spirits of turpentine, or the embrocation prescribed at p. 1152, of the third volume, applied in the way now stated; the access of air to the wounded vein being unsucessfully prevented.

61. Whilst either of these embrocations is being applied, internal means should be prescribed with due reference to the state of vital power and vascular action, and to existing morbid sensibility and irritability. Care, however, should be had that the medicines prescribed are not such as may occasion vomiting, lot or diarrhoea of the bowels, as either or both will promote the passage of the products of inflammation into the blood, or render these products more likely to pass into the circulation. The medicines prescribed internally during this period, should have for their main objects to prevent the extension of inflammation along the veins, and to assuage pain and irritability: the former of these can be attained only by developing vital power and resistance; and the means best calculated to attain this end may be conjoined with those which affect the latter object. With these intentions I have not frequently prescribed the following, varying the individual substances with the varying circumstances of individual cases.

No. 370. R Olei Terebinthiniæ, 3s.; Spiritus Etherei Sulphurici comp. (vel Etherias Hydrochloris, 3s.) Tinct. Camphoræ comp. 3s.; Olei Cajuputi, 3s.; Pulvis Traganthi, comp. 3s.; Pulvis Glryanæ, comp. 3s.; Syrups Roosæ et Syrupus Toluænit, éa. 3s.; Infus. Cantharid., 3s.; (vel Infus. Cinchoni) ad 8fis. Miecr. Caplat ager Cochlearis i. vel ii. larga 4tas vel 5tas horas.

62. An apparently high or tumultuous vascular action, or an open, broad or even bounding state of the pulse, should not deter from a recourse to these or similar means; for these phenomena will much more readily subside under the influence of these, than those of an opposite nature; for vascular action is often the greatest and the most
tumultuous, when vital power is most deficient, especially when any part of the vascular system is inflamed. By developing and increasing vital power by suitable means, in these circumstances, we more readily overcome or appease morbidity increased vascular action. Although it is not desirable that the veins should be excited, still the depurating functions should neither be impaired nor arrested. Hence the remedies may be combined as in No. 368., in order to prevent this result; or equal parts of castor oil and oil of turpentine may be taken on the surface of an aromatic water, or these substances, in larger quantity, may be administered in an enema.

53. During the local limitation or period of the disease the system sympathizes with the local morbid action, occasioning much febrile disorder, which, although the above means may not for some time either diminish or increase, will not pass into that adynamic condition which readily supervenes upon a lowering treatment of phlebitis, owing to the effects of such treatment upon the local morbid action and to the passage of the inflammatory products into the blood. If, however, notwithstanding the means, the catarrh, and the inflammation of the vein either extends, or produces a puriform fluid, or in cachetic habits of body an ichorous or venous exudation, which readily passes into, and commingles with, and contaminates the blood, the most strenuous efforts should be made to support vital power and resistance, to counteract or neutralise the injurious action of the contaminating materials, and to remove them from the circulation by means of the depurating organs.

54. In this, the second or contaminating period of the disease, the treatment will necessarily vary with the states of the several depurating functions — of those of the skin, bowels, and kidneys. The excretions from these must be frequently examined; and the means of cure prescribed appropriately to their several conditions. If the urine presents an acid reaction, the mixture No. 371. last advised may be continued, with or without the addition of the chloride of potash or carbonate of lime. If the urine be neutral, or alkaline, or contain the phosphates in excess, then the nitro-muriatic acids may be given instead of these and of the alkalies contained in that prescription. If the skin be dry, or parched, or hot, the mixture No. 368. will generally increase the cutaneous functions, especially if promoted by suitable diluents (§ 56.). When it is manifest that neither the hepatic nor the intestinal functions are sufficiently discharged, then the pills already prescribed may be given; or pills containing a full dose of calomel and camphor may precede either them, or the castor oil and turpentine draught and enema above recommended (§ 52.). If the bowels become inordinately relaxed, the tonics already mentioned or others may be conjoined with astringents, small and frequent doses of creosote, absorbents and acetanies, and with punctures or incisions. If any irritation of the mouth of the ulcer be present, the use of camphor; or with any of the several remedies advised for Diarrhea or Dysentery (see these Articles), according to the features of the case. It should not, however, be overlooked, that relaxation of the bowels is a mode of vascular depression, especially when the hepatic functions are duly performed, and that this relaxation should not be arrested, unless it increase, or reduce the patient; but be moderated only, constitutional power being duly supported by the means already prescribed, aided by suitable nourishment, and by a sufficient supply of wine, at regular intervals.

55. In these and similar cases evincing not only great depression of vital power, but also more or less deficiency in the quantity and quality of the blood, the quinine, or the decoction of cinchona, chalybeate preparations, and other restoratives, may be given in increased or more frequent doses; and wherever pain, oppression, or uneasiness may be manifested, the embroctions advised above should be applied and renewed from time to time. In these and analogous states the tonics will be advantageously conjoined with camphor, ammonia, aromatics, &c., and with opium in moderate doses.

56. The diet, regimen, and beverages, prescribed for the patient ought to be restoring, and calculated to promote nervous power. Rich wines, brisik, bottled malt liquors, or bitter ales; soda-water or Seltzer-water with wine; the saline and chalybeate mineral waters; spruce beer and weak tar-water; Carraw or lime water with warm milk, &c., are the remissives which will be found most beneficial. From ventilation, and a warm, dry, and pure air are also most important aids of medical treatment. In most respects the treatment of the second stage of phlebitis is the same as that which is most efficacious for consecutive abscesses (see art. Abscess, §§ 62. et seq.), for the effects of absorption of morbid matter from diseased organs and structures (see Absorption, §§ 15. et seq.); for inflammation of the Lymphatics (§ 17. et seq.), and for the consequences of animal or food Poisons (§§ 427—456).

II. STRUCTURAL LESIONS OF VEINS.—CLASS.

IV. CLASS. III. ORDER (Author in Preface.)

57. a. Inflammation of veins occasions redness, or a reddish brown or violet tint of their coats. But similar changes, usually however of a more uniform character, are often produced in these vessels after death, by the imbibition of the colouring matter of the food. Indeed, this is the most frequent source of the different shades of colour observed in the veins, these shades varying with the state of the blood, and with the period after death at which the examination had been made. The redness proceeding from this source is much more frequently met with in the veins than in the arteries, evidently owing to the constant presence of blood in the former after death. This change, however, differs, in pervading all the coats of the veins, whereas it is generally confined to the inner membrane of the arteries. Redness, therefore, unaccompanied with other changes, cannot be considered as a proof of disease.

57*. The veins, like other parts of the body, present alterations arising from the secretion of coagulable lymph or albumen. This plastic and organisable matter, in which a number of morbid formations originate, is commonly found in the veins, either extended into membranes or accumulated in amorphous masses. It is always to be viewed, particularly when connected with redness or vascular injection, as a result of the inflammatory act. The experiments which M. Gendrin instituted with the veins as well as upon the arteries have illustrated this point.
68. b. Coagulated lymph is found — 1st. In the interior of the veins; 2nd, between their coats; and 3rd, on their external surface. When this is considerable, or obliterates the canal of the vessel, it is said to be partially organized, and is changed to cellular tissue, if the life of the patient continue for some time. When the lymph is secreted in smaller quantity, so as not to interrupt the circulation in the vessel, it generally presents the form of a firm albuminous layer, beneath any trace of organization; but in some instances, as pointed out by Ramm, Genbrin, and Andral, it forms a delicate membrane, and presents evident traces of organization, being traversed by minute vessels. The surface of the vessel opposed to these membranes is sometimes, most commonly in the more recent cases, of a deep red colour; but in other cases, particularly those of older date, it is perfectly colourless. The coagulated albumin thus formed in the interior of the vein may constitute small patches merely, or small circumscribed masses, or a complete continuous layer extending through the substance of the vessel. The polyposous concretions described by Rees (Fieberlehr, bk. ii, pp. 215—297) belong to the second of those varieties.

59. c. Purulent matter is frequently found in veins. M. Andral states that coagulable lymph may gradually lose its physical characters, and be insensibly transformed into pus. That this may happen previously to the coagulation of the lymph, is possible; but we have no satisfactory proof of its occurrence, and least of all, after the coagulation of this fluid has taken place. Indeed, it must not be supposed that the purulent matter formed in the veins is generally, or even frequently, produced in this manner. When it is found in the veins, it evidently does not proceed from a transformation of the plastic matter already noticed, but from a modification of the morbid action of the extreme vessels which secreted that matter, and from a change in the vital condition and cohesion of the internal membrane of the vessel; this membrane being somewhat softened, and frequently tumified or thickened. When the purulent matter is formed from the vein itself, it is found — 1st, in the cavity of the vessel; 2nd, infiltrated between its coats, and 3rd, surrounding.

60. The purulent matter formed in the interior of the veins, is, however, more frequently conveyed there from some other part with the blood, than secreted by an inflamed vein. When secreted in a vein, it is either pure, or mixed with the blood, or coagula. When pus is found connected with coagula, it has been, in some cases, external to them, and in others, contained in them. This latter phenomenon has led to some speculation on the part of certain pathologists. M. Andral believes that pus contained within a coagulum has been formed there in consequence of some peculiar modification of the blood itself. But this is merely a supposition, and is opposed by the consideration that the blood-globule can hardly be changed to a pus-globule, either during or after the coagulation of the blood.

61. The irritation and inflammation producing suppuration of veins, arise from various causes. These are stated when treating of inflammation of these vessels (§§ 6 et seq.), where I have shown that inflammation originating in a part of a vessel may extend both towards the heart, and in the course of the smaller branches. The connexion of redness, thickening, softening, &c., of the coats of veins, with the formation of purulent matter in them, has been fully illustrated by the researches of Ribe, Davis, Velpau, Genbrin, Louis, Arnot, Lee, Tonnelé, and Dance; and similar appearances have repeatedly come before me in the examination of fatal cases of puerperal diseases. But pus is often formed in the veins, without any change of structure of their paries; particularly in those veins which arise in parts in a state of suppuration. I have often observed in such cases that the veins of puerperal patients contained purulent matter either in its cavity or in its sinuses, the uterine veins, and some of the veins into which they run, nearly filled with this matter. Similar appearances have been noticed by Dance, Louis, and others. Abercrombie and Tonnelé have found pus in the sinuses of the dura mater, in cases of caries of the bones of the head, &c. Pus has often been found in the veins near disused joints, suppurating fractures, and unhealthy stumps, by Ribe, Velpau, and others. Blanchard long ago found pus in the vena cava, in a case of abscess of the liver. M. Genbrin found pus in the veins in the vicinity of ulcers in the intestines. M. Andral has met with similar appearances. I have stated in the Article Diætery, that abscesses of the liver sometimes complicating that disease not infrequently proceed from the absorption of pus from the irritated intestines into the veins, which, circulating into the vena porta, excites diffusive or anesthetic inflammatory action, rapidly followed by the formation of purulent matter in the substance of the liver. This view is confirmed by the researches of M. Rees, who has demonstrated that the villi of the intestines are principally composed of minute branches of veins. M. Andral, found, on the examination of a case of diseased intestines and liver, the vena porta and its branches lined with a false membrane. When purulent matter is formed in a part, and afterwards conveyed into the veins, as in the instances now alluded to, their coats are in some cases apparently sound, and in others inflamed or softened, or their interior is lined with a false membrane, &c. In the latter cases, either the inflammatory action has extended itself to the veins from the part primarily diseased, or the morbid secretions which have passed into them have irritated and inflamed their internal membrane, at the same time that they have induced serious changes in the blood and system generally.

62. In aseptic or aseptic states of phlebitis, or when the cause is of a poisonous or septic character, the veins, in the interior of the inflamed vein is neither plastic nor purulent, and is so entirely of an ichorous and liquid
nature as to mingle readily with the current of the circulation, and to rapidly contaminate and poison the blood and the soft tissues, and to destroy life. In such cases discoloring of the inner surface, and softening and thickening of the coats of the vessel affected, with an altered appearance of the blood—a dark, semi-coagulated or uncoagulated condition of this fluid. In these cases the blood is rare, or if at all, coagulated, or very imperfectly coagulated in the diseased vein or veins, there is no plastic exudation on the internal surface, and no trace of pus in the vessel.

The injurious operation of this ichorous exudation is accelerated by the circumstance of its failing to produce coagulation of blood in the vein; for when the exudation is plastic or purulent a coagulum is generally formed by these latter exudations; and this coagulum often prevents the extension of the inflammation and contamination of the blood and its consequences, whilst the ichorous and more liquid exudation hastens both these most dangerous or fatal results.

62. Thus the morbid states of veins may originate either in themselves or in the parts in which the veins commence; but, whether they be thus primary or secondary, or whether they exercise a powerful influence on the system, and on distinct organs, both through the medium of the blood, and by continuity of tissue.—1st. Purulent matter secreted in an inflamed vein, or conveyed into the veins from an adjoining part, may mix with the blood, occasion febrile symptoms of an adynamic character, generally with colliquative perspirations or diarrhoea, and be thus eliminated from the circulation nearly as fast as it passes into it, by the several emunctories. 2nd. This matter, when once carried into the circulation, may be secreted from it into the parenchyma of some organ, the cavity of some joint, or even into cellular or muscular parts. 3rd. Purulent matter circulating in the vessels, whether the pus globules be metamorphosed or no, during their circulation, may induce inflammatory irritation, or such a state of the capillaries of an organ or part of the body, as may be rapidly followed by the formation of purulent matter in such part, or by disorganisation. 4th. Inflammatory irritation excited in the internal membrane of a vein, more especially the atraumatic forms, may extend in every direction to other veins, especially in that of the heart, and thus implicated other organs or parts. This diffusive form of phlebitis generally occurs in debilitated or unhealthy states of the frame, or when the disease is consecutive on other maladies, or caused by septic or poisonous agents. 5th. Inflammatory disease of the internal surface of the veins will give rise to a secretion varying with the state of the vital powers of the system, and this secretion carried along, and mixing with the circulating current, will remarkably influence those powers and depress or otherwise modify them. 6th. Inflammation attacking all the coats of a vein is more likely to occur in a healthy body than that confined to the inner surface, and is more commonly productive of an effusion of coagulable lymph, which tends to limit the inflammation, to prevent the admixture of the products of inflammation with the blood, and thus to preserve the blood from contamination. 7th. This atheic form of inflammation most frequently occasions obstruction and obliteration of veins; and, if the obliteration be seated in large veins, serious local and general effects may result, owing to the mechanical obstacle thereby presented to the circulation.

63. d. Softening of the inner membrane of veins is often observed, and is generally accompanied with redness when it is the result of inflammation. Sometimes the softening is so great that the inner surface of the vessel is readily reduced to a pulpy state by gently scraping it with the back of the scalpel.

64. e. Thickening of this membrane is often associated with the foregoing changes; it may be either partial or general. In the former case the inner surface of the vessel presents an uneven appearance. But softening and thickening of the inner membrane of the veins are not always connected with redness; this membrane may present either of these alterations, or both of them, accompanied with paleness or with different shades of colour.

65. f. The valves of the veins are subject to the same alterations as the inner membrane. They are often deprived of their transparency, primary or secondary; presenting the appearance of irregular fringes crossing the cavity of the vessel, and having generally coagulated blood adhering to them. 66. g. The middle coat of veins is often softened, generally at the same time as the inner. When this is the case, the vessels are torn with great ease. This coat is also subject to atrophy. When this exists the vessel presents an extraordinary degree of tenuity. Hyper trophy of the middle coat has been minutely described by M. Andral. When this change exists, the coat is more distinctly visible, and its longitudinal fibres more evident. When the hypertrophy is considerable, this coat loses its transparency, acquires a yellowish colour, and becomes, to a certain degree, elastic, so that, when cut across, the vein remains open as an artery, to which it closely approaches in appearance. On minute dissection, however, the middle hyper trophy of the vein, as well as that of the internal fibres, nor does it possess the same degree of elasticity as the middle coat of arteries. M. Andral states that he once detected, as he believes, muscular fibres in the vena cava inferior, near the heart; the vena cava was greatly hypertrophied. The hypertrophy in this case developed a structure similar to the natural condition of the vessel in some of the lower animals. In the horse, the structure of the vena cava near the right auricle is evidently muscular.

67. The middle coat, however, may be much thickened without actual hypertrophy or development of its fibres. This may arise from a deposition of fibrous lymph in its texture, which becomes solidified by the absorption of its serous portion. M. Andral accounts for this change by supposing that a quantity of blood accumulates in its tissue; that the colouring particles are absorbed, and the white fibre remains behind in a solid form, combined, molecule to molecule, with the costs of the vein, presenting the lardaceous appearance described by authors as a particular tissue; but instead of having recourse to this complex explanation, would it not be preferable to consider this alteration as a result of chronic inflammatory action in the coats of the vein?

AV 2.
68. h. The external coat of the veins is subject to the same changes as have been observed in the external coat of arteries, and which are described in that article (§ 44.). These alterations of both the middle and external coats are common also after embolism in the latter variety. In venous tumours the external coat is often involved. The author adds that the tumours occasioned by dilated veins disappear spontaneously. When this occurs, the veins are generally obliterated. Some of the above kinds of varic, according to this pathologist, depend upon increased activity, others upon diminished activity of the nervous process. Such, however, can be rarely the case. They are generally the results of pressure on the venous trunks into which the varicos veins pour their blood, or of some other obstruction to the circulation through the former vessel. In this case the varicos veins are not only greatly dilated and elongated, but their paries are also hypertrophied.

72. (h.) Contraction and obliteration are, according to M. André, much more common than their dilatation. These lesions are occasioned,—1st, by obstruction in the interior of the veins; 2nd, by causes seated in their paries; and 3rd, by causes external, virulent, or otherwise, directly or indirectly from tumours, &c. The most frequent cause of the obliteration of the canals of veins is the spontaneous coagulation of the blood within the veins. That the blood may coagulate, during the life of the patient, within a vein or portion of a vein, and even within the sinuses of the dura mater, has been proved by the researches of many pathologists, particularly by Meckel, Gendrin, Bouillaud, Rieue, André, Chouvelier, Arnot, Reynaud, Rokitanski, myself and others. It has occurred in several which have come before me in practice, especially in the advanced stages of low fevers, of acute rheumatism, of purpural diseases, and in dysentery. It is often difficult to assign the particular cause of the coagulation. It is, in some cases, apparently owing to the low state of the vital energies and their effect on the blood. In other cases it is probably occasioned by the morbid state of the valves which are arrested (§ 65.), or to lesion of the internal paries of the vessel. Most frequently, however, it proceeds from coagulable lymph or pus secreted from the internal surface of the vessel; this morbid secretion adhering to the inflamed surface producing it, entangling the fibrous and colouring parts of the blood, and thus forming a coagulum which either partially or entirely obstructs the canal. This coagulum generally varies in colour, density, and firmness of adhesion to the sides of the vessel; and it increases in bulk until the passage is entirely obstructed by it. Occasionally the coagulum becomes, in some respects, organised. Some of the pathologists whose names I have just adduced, suppose that these coagula live precisely as the veins in which they are formed, and, like every other part endowed with life, keep up a constant process of nutrition and secretion, and are also liable to become diseased.

73. The canal of a vein may be altogether obliterated, and the vessel reduced to a fibro-cellular chord. This seems to be effected in a similar way to that observed in arteries. Obliteration of large venous trunks gives rise, as observed in arteries, to a collateral circulation, kept up by means either of small veins, or of one vessel that has acquired an unusual size. The most
VEINS—ORGANIC LESIONS OF.

74. b. Osseous or calcareous formations are rarely met with in the coats of the veins. They have, however, been observed by Morgagni, Walter, Murray, Bailie, and Tiebout, and more recently by Macartney, Beclard, and Andral, in the femoral and saphena veins. Sometimes these concretions protrude into the cavity of the vessel, either bursting its internal membrane, or carrying this membrane before them. In either case they may attach to the intima of the vein and lodge there, without any attachment to the sides of the vessel; for, in the latter case the membrane may contract behind the concretion, forming at first a peduncle attaching it to the vessel, which at last is ruptured or absorbed.

75. These concretions have received the name of Phlebolithes; they vary from the size of a millet-seed to that of a pea. They have sometimes been found in the centres of coagula, which had evidently been formed around them. They have been observed by Columbus, Walter, Semmerring, John, and Langstaff. E. Tiedemann has described them minutely. Those which he has observed, as well as those noticed by the pathologists just now named, were formed in the uterine and hemorrhoidal veins. Tiedemann and Krotatsky state that they are formed of concentric layers of the phosphatic and carbonatic lime of the vein, united by albuminous matter, around a minute clot or coagulum; and deny that they are formed in the way which I have just stated (§ 74.); and contend that they have been produced by a sort of crystallisation, or deposition, of the earthy particles contained in the blood, around a nucleus which had formed in the nearly stagnant blood in the veins. M. Andral also considers it possible that they may have been formed in the blood itself. It is difficult to assign limits to the range of possibilities, without relation to the faith of those for whose belief they are adduced; but the question is, whether or not these concretions have ever been actually ascertained to have been formed in this manner. I believe that no such fact has ever been adduced.

76. m. Fatty, suety, and atheromatous deposits have been found in the parietes of veins, but not nearly so frequently as in the coats of arteries, where I have first described them (§§ 59, 60.). Bontius states that he has met with large masses of fat in the vena cava, obstructing its canal. I have sometimes found fatty and suety deposits between the coats of the vena porta; and M. Andral has noticed similar deposits in this vein. 77. m. Tuberculosus does not occur either in or on the coats of the veins. If any tuberculous matter, or substance resembling this matter, be found within the veins, it can proceed only from imbition or absorption. But before this matter can be imbied it must be softened, or metamorphosed, and thus have lost the tuberculous character.

78. a. Cancer is met with in veins in two ways:—1st. The walls of a vein may be attacked by a cancerous or carcinomatous growth, penetrated by, involved in, and closed or altered by this growth. The portal, renal, hepatic, and other veins may be thus implicated;—2nd. The cancerous matter, especially when existing in other parts of the body, may constitute in a large vein, a variously formed mass, attached to the interior of the vessel, that may either partially or entirely fill and obstruct the canal. This cancerous formation obviously arises from the imbition or absorption of the cancerous matter or cells into the veins, where they attach themselves and collect into masses of various sizes and forms. The oedema and swellings occurring in the last stages of carcinoma are, in some cases, attributable to this formation in the veins, and in other cases, produced by the imbition of the cancerous matters.

79. p. Gaseous fluids have occasionally been remarked in the veins. In some cases they have proceeded from incipient putrefaction, but in others this could not have been the case. The vapours and gaseous exhalations from blood very recently taken, or at the time of its being taken from veins, and those found in veins after death, have not been sufficiently examined. They manifestly are such as demand a much stricter investigation than they have hitherto received.

80. q. Entozoa have been often found in the veins of the lower animals. The strongylus and flaria have been detected in the horse. M. Andral found individuals of the class Nematoidea in the vessels of a porpoise. In one only case he found Acephalocysts (hydatids) in the pulmonary veins.

CLASS. I. ORDER (Anther., in Prepate.)

1. DEFINIT.——Specific inflammations, or ulcerations, or both, affecting primarily the organs of generation of both sexes, and very frequently the whole frame, at subsequent and sometimes at remote periods, and propagated by contact.

2. Viewing venereal diseases as consisting of two very distinct forms, viz. those in their primary character and in their consequent action— I shall very briefly notice, first, generaeva, or blemmyaria, or more correctly, Blemmyaria specialis, or virulentas, and afterwards syphilis, or Syphilis veneris. The relations between these two venereal diseases have been for ages much discussed by both physicians and surgeons, and are not even now entirely disposed of. They, however, possess this in common, that they are primarily seated in the sexual organs, with very few exceptions; that they generally result from impure sexual connexion, or from contact, and that they are primarily either inflammatory, or ulcerative, or both; and that in many instances the frame becomes affected or contaminated by them, but in very different forms and grades, and much more
frequently in the one form than in the other. These constitutional effects render them of equal importance to the physician and to the surgeon; and although both may sometimes require surgical appliances and aids, still they may be both cured by the prescriptions of the physician only, which alone are appropriate in the consecutive states of the disease.

4. Definition. — A specific inflammation of an acute form, affecting the mucous surface of the urinaries and sexual passages in both sexes, with a copious puriform or mucous-purulent discharge, propagated by contact, and in some instances occasioning severe consequences.

5. Description. I have shown, in the article Vagina and Vulva, that those parts are often the seat of a purulent or mucous-purulent discharge, which presents the following states or forms: — 1st. Leucorrhœa, or Blemorrhagia, the discharge arising from irritation or inflammatory action, of a non-specific nature; 2d. Acute Gonorrhœa, or Blemorrhagia virulentæ, the discharge being the result of a specific inflammation, caused by the contact of this discharge, which, in an examination by the speculum, a large warty growth, soft, red, and vascular, was found two inches and a half from the orifice of the vagina. This growth was two inches in length, and an inch and a quarter across the base, springing from the anterior wall. It was removed by the knife; immediate relief, and complete recovery soon afterwards ensued.

8. Gonorrhœa in the Male. This is not only a very painful and troublesome complaint, but, if injudiciously treated, it may induce changes, — or, rather, the treatment improperly adopted may occasion lesions unconnected with the disease, which may embitter, or even shorten the life of the patient. And during a somewhat lengthened period of observation I can assert, that numerous instances have become known to me of attempts made to effect a speedy cure having been followed, caused by ex-digitation and dangerous results. The complaint usually commences from three to ten days after morbid contact; and the shorter the period of its incubation the more severe the attack; the stronger dose of the virus hastening the effects. A slight itching is at first felt, then an irritation at the opening of the urethra, and afterwards a smarting pain, more or less severe, upon micturition. The lips of the urethra become tumid; a thin discharge, at first scanty, but soon afterwards more copious and puriform, flows from the passage. The corpus spongiosum urethrae becomes thickened and unyielding, owing to inflammatory exudation into it; and when erection of the penis occurs, a bending downwards, or chordee, is produced. Hemorrhage sometimes takes place during this state and affords partial relief; and occasionally irritation extends from the urethra to the glands of the groin, causing slight swelling, which very rarely goes on to suppuration, unless in scrofulous subjects.

9. A form of gonorrhœa — gonorrhœa sicca — is occasionally met with, both in the male and female, and has been described by Mr. Acron and Dr. Davitt; in which the mucous membrane of the female organ is red, swollen, and
tender, but free from discharge. In the male there are severe scalding and pain on passing the urine, painful erections, the lips of the urethra being red and swollen. This form of the disease has been called acute (though not always) with fewer of the symptoms of acute inflammation. In some instances, the constitutional affection is extremely anomalous, and characterised by fever and continuous rigors, or by slight remittent or intermittent rigors and paroxysms of febrile reaction. These occur in the female more especially, and those about to be noticed, are chiefly to be ascribed to the local and constitutional influence of the virus or infecting agent, an influence manifested in some cases more prominently than in others, and not observed in cases of simple urethritis. Certain of the above complications are, however, merely the local extension of the gonorhoeal inflammation, often owing to the causes above alluded to. Other complications or consequences of the disease are of a constitutional and very serious nature. Mr. Holmes Coote, in a work published whilst this was being written, corroborates the view I have taken in the articles on Uterus and its Appendages (§§ 43, 53, 122, et seq.), and Vagina and Vulva (§§ 8, 13, 38). These consequences are, chronic gonorhcea, suppuration or abscesses in the labia, soft vascular worms (§§ 6, 75), gonorhoeal inflammations of the cervix uteri, extending to the cavity of it and of the uterus along the Fallopian tubes to the ovaries, and even to the peritoneum; and, in rare instances, to the uterine veins. Gonorhoeal ophthalmia, and gonorhoeal rheumatism occur not less frequently in the female than in the male. The modes of gonorhoea sometimes observed in males are, 1st, Balanitis (from Balas, glans), or gonorhoea externa, is an inflammation of the surface of the glans and inside of the prepuce, with profuse purulent discharge and excretion of the crusts. This affection may be a complication of gonorhoea, or may exist independently of it. In the former case it is produced by the gonorhoeal virus; in the latter by the want of cleanliness, and by the excoriations caused by the secretions of the part, which have become acrid by retention. In these latter cases the excoriations may be mistaken for chancre. 2d, Pemphigus and Paraphymosis occasionally arise, owing to the swelling of the glans and prepuce. Edema of the prepuce presents a semi-transparent or diaphanous appearance. These states, although often complicating gonorhoea, not infrequently occur independently of it, especially as a consequence of self-pollution; and in some instances they lead to very serious results. They furnish additional reasons, to others which may be adduced, as to the propriety of circumcision during infancy. 3d, Irritation or inflammation of the lymphatic vessels, extending to the glands of the groin, is but an association of the disease; but the affection of the lymphatics may be so slight as to be imperceptible, although the glands may be much swollen, inflamed, or even suppulsive. 4th. The mucous follicles of the urethra may be inflamed and obstructed, and may even suppurate and burst either into the urethra, or externally, or both. In these cases, very serious obstruction to the discharge of urine may occur. 5th. The inflammation may extend along the urethra to the prostatic gland and neck of the bladder, and even along the ureters to the kidneys; or it may give rise to acute abscess of the gland and great suffering, especially during micturition, to strictures, &c. 6th. More frequently, inflammation extends along the vas deferens, causing swelling of the epididymis, or swelled testicle.

12. Gonorhoea is always most severe on its first occurrence, and in young and robust subjects and in the irregular constitutions of sinews and habits. In these it is often attended by severe inflammatory fever and disorder of the urinary functions; and it may even prove dangerous to life, by inducing extensive inflammation and abscesses in the vicinity of the prostate and bladder. But after repeated attacks the urethra becomes irured to the disease, and each subsequent infection is generally mild (although not always), attended with fewer of the symptoms of acute inflammation. In some instances, the constitutional affection is extremely anomalous, and characterised by fever and continuous rigors, or by slight remittent or intermittent rigors and paroxysms of febrile reaction. These occur in the female more especially, and those about to be noticed, are chiefly to be ascribed to the local and constitutional influence of the virus or infecting agent, an influence manifested in some cases more prominently than in others, and not observed in cases of simple urethritis. Certain of the above complications are, however, merely the local extension of the gonorhoeal inflammation, often owing to the causes above alluded to. Other complications or consequences of the disease are of a constitutional and very serious nature. Mr. Holmes Coote, in a work published whilst this was being written, corroborates the view I have taken in the articles on Uterus and its Appendages (§§ 43, 53, 122, et seq.), and Vagina and Vulva (§§ 8, 13, 38), as to the specific nature of gonorhoea. This very able and rising surgeon remarks,—"Is the disease the consequence of the application of a simple irritating fluid to the mucous membrane, or is there a morbid poison acting on the parts locally, and capable of being absorbed into the system? I must confess there appears to me to be a most marked difference between simple urethritis and true gonorhoea, as we daily see it among those exposed to contagion." Gonorhoea in some cases occasions peculiar secondary affections, which never proceed from simple urethritis; and not only is it occasionally followed by the local complications just mentioned, but also by one of the very severe forms of inflammation of the conjunctiva (see art. Eye, Gonorhoeal Inflammation of, §§ 50, 60, et seq.), by the most severe and obstinate form of rheumatism (see art. RHEUMATISM, gonorhoeal (§§ 44, 150)), and by a form of papular eruption. The occurrence of purulent ophthalmia, or of rheumatism, or the extension of inflammation from the urinary bladder along the ureters to the kidneys, is of a most serious nature, as respects both the immediate effects and the more remoter consequences.

14. ii. Treatment. A. Of Gonorhoea in the Female. A copious use of diuretics and demulcents; a farinaceous and vegetable diet; avoidance of fermented and spirituous liquors, and of salted provisions; a recourse to alkaline and refrigerant substances in mucegious drinks, and repose on a cool couch or mattress, are generally sufficient to remove the severer symptoms in a few days, especially when aided by the following local treatment judiciously advised by Dr. Drury:—"During the acute stage, rest in the recumbent posture, fomentations of decoctions of poppyheads with chamomile flowers, frequent ablutions, lubrication with lard or cold cream, and very frequent sponging with a weak solution of alum, a piece of lint dipped in which should be inserted between the labia, with laxatives and diaphoretics, are the measures until heat, pain, tenderness, subside; afterwards the urinary discharges should be kept as small as possible, and sulphate or acetate of zinc should be used, as recommended for the other sex, and they should be continued for some time after all discharge has

---

In order to understand the full context of the text, it appears to be discussing the complications and treatment of gonorhoea, a sexually transmitted infection. The text mentions various symptoms, complications, and treatment methods, including the use of various medications and rest. It also notes the effects on the female population, mentioning specific complications like gonorhoeal ophthalmia and the involvement of the lymphatic vessels and glands. The text emphasizes the importance of cleanliness and the risks of self-pollution in the spread of the disease.
VENereal Diseases.—Treatment of Gonorrhoea.

15. If the disease become obstinate and chronic, the vagina and cervix uteri should be examined by the aid of the speculum, as the disease may be prolonged by lesions of the cervix or of its canal; and in this is the case, the means advised for such lesions, in the article Uterus (§§ 124, 125.) should be resorted to. In chronic cases, the solution of sulphate of alumina, or decoction of oak-bark, or both combined, may be used as a lotion. Copaiba and cubebas may be given thrice daily in a mixture with mucilage, the spirits of nitric ether, and either mint-water or camphor jalap, in the chronic, as well as in the advanced progress of more acute cases. In the former, preparations of iron, especially the tincture of the sesquichloride of iron, or the tincture of the ammonio-chloride may be preferred. In irritable and sanguine temperament, camphor conjoined with nitrate of potash, with aconit and luneville, is often of much service, and may be prescribed in the form either of pills of a mixture or draught.

16. B. Treatment of Gonorrhoea in the Male.—(a). Dr. Druitt has advised, as a prophylactic treatment, that a person exposed to the chances of infection should, as a matter of precaution, have the urethra with a syringing of some astringent lotion. I much doubt the complete success of this plan, or of the more usually adopted one of micturating immediately after sexual connection; both plans may, however, be often successful. If any fissures or excoriations are perceived they may be touched with luna carust and dry lint may be applied.

17. (b). The abortive treatment of gonorrhoea, or an attempt to cut short the attack by means of strong injections, has been advised by some experienced surgeons. Ten grains of nitrate of silver, or four grains of the chloride of zinc, to the ounce of distilled water, have been prescribed with this object, when the disease is only commencing, and before scalding on mucituration is experienced, or when the acute symptoms have passed. Mr. Acrost employs the nitrate of silver, and without any of the consequences which have attended the two injections performed by himself with due precautions. He never prescribes this treatment in cases of a first infection; and he states that he has not observed the injurious effects which have been supposed to result from it. For the modes of using, and the precautions to be taken when using, this treatment, I must refer the reader to Mr. Acrost's able work, Mr. Holmes Coote considers it not quite free from danger to the urethra; and he remarks that it should be remembered that it is in cases where the structures of the urethra are damaged that structure occurs; the usual effects of gonorrhoea, in their acute form, pass away, if not aggravated, without leaving any structural change. "At the commencement of the disease large doses of the tincture ferri sesquichloridi, or of the citrate of iron and quinine, have been pronounced effectual in cutting short the discharge; and such remedies possess the advantage of inflicting no damage, if they do not produce the anticipated amount of good."

18. (c). In the first or early stage of gonorrhoea the antileptic diet and regimen should be strictly enforced; and demulcent containing alkalies and refrigerants freely allowed, with the other means already noticed ( §§ 14, et seq.). Cooling aperients ought to be taken from time to time; walking and horse-exercise should be prohibited, and the patient confined to a cool sofa or mattress. The penis and scrotum should be supported by a suspensory bandage, and be kept constantly wet with tepid or cold water. If the acute symptoms have not appeared, M. Brown recommends, according to Dr. Druitt, the following plan, in order to arrest the course of the disease:—Let the patient inject the urethra regularly once in every four hours with a solution of two grains of nitrate of silver in eight ounces of distilled water, let this be repeated twelve times, desisting, however, sooner if the discharge is rendered thin and bloody, which is the ordinary effect of the nitrate. Then let an injection of the sulphate of zinc be substituted, and be continued until the discharge ceases. At the same time the patient should take a mild aperient, and after it, three times daily, a dose of copaiba or cubebas. He should continue a strictly antileptic regimen for a week or ten days after all trace of the discharge has disappeared. The penis should be wrapped in a piece of rag dipped in water. Dr. Druitt proceeds to remark, that the "manner of injecting is of no small consequence, as the efficacy of the lotion depends entirely on its application to the whole of the diseased surface; and, as Dr. Graves observes, the ordinary opinion that gonorrhoea is limited to the anterior extremity of the urethra is unfounded and mischievous. The patient should be provided with a glass syringe, with a long bulbous extremity, and having filled it, should introduce it for about an inch with his right hand. Then, having encircled the glass penis with his left forefinger and thumb, so as to compress the urethra against the syringe, and prevent any of the fluid from escaping, he should push down the piston with his right forefinger, letting the fluid pass freely into the urethra. The syringe should now be withdrawn, but the orifice should still be compressed, and the fluid be retained for two or three minutes; after which, on removing the finger and thumb, it will be thrown out by the elasticity of the urethra. It is twelve weeks or a man's while to see that the injection is properly used."

19. (c). In the second stage the diet and regimen already advised should be continued. The patient may drink soda-water, barley-water, linseed tea, gun-water, and other mucilaginous fluids, containing alkaline carbonates and sedatives, and the bowels should be kept freely open. If much pain or chordee be complained of, the following pills may be taken night and morning, and the mixture occasionally through the day:—

No. 372. B. Camphor 3; Potassae Nitratis 3; Ectr. Hyoscyami 3; Mucilag. Acaciae q. s. Miscce ad fillias maxm. (Divide in pilias 3 x 3.)

No. 373. B. Potassae Bi Carbonis 3; Potassae Nitratis 3; Spiritus Arctii 3; Tinct. Hyoscyami 3; Mucilag. Acaciae 3; Syrups. Amandae 3. Miscce ad fillias maxm. Mist. Camphor ad 3 fillias.)

No. 374. B. Liq. Ammon. Acetatis 3; Spiritus Ethers Nitratis 3; Potassae Nitratis 3; Tinct. Hyoscyami 3; Mucilag. Acaciae 3;—syrup. Amandae 3; Mist. Camphor ad 3 fillias.)

Larga, 3x3 ad 3x3 horis.

20. The last of these prescriptions will be found serviceable in the most acute or inflammatory cases, and when the urinary organs become affected. In these cases a number of leeches should...
be applied to the perineum, or above the pubes, or near the groins. In this stage of the disease injections should not be prescribed. For first attacks, and in young, strong, plethoric, or irritable subjects they may be injurious. Refrigerants, diffusibles, demulcients, alkalies, and sedatives, are then chiefly required.

21. Dr. Duverri advises that the bowels should be opened by a dose of calomel at night, and some castor oil in the morning; and that a grain or half a grain of calomel, and one eighth of a grain of tartar emetic, and ten grains of Dover’s powder, should be given every night whilst there is much pain and choree. As soon as the patient is free from fever, he should take copaiba or cubebis. The former, in capsules, may be given before a meal, as it is then not likely to cause eructation.

Mr. Acton prescribes copaiba and cubebis in the following combinations:

22. The last of these is altered from Mr. Acton’s prescription, and the dose of camphor reduced one half. Cubebis, when taken in very large or frequent doses, generally diminishes the discharge, and remarkably relieves the other symptoms of the disease; but when employed alone, the disorder often returns after some time, especially if it be relinquished, or the dose much diminished. Cubebis should therefore be conjoined with copaiba, or other substances, in mucilaginous mixtures; or the tincture of cubebis may be substituted for the powder, as in the following draught:

23. d. Several unpleasant complications occasionally appear in the course of this stage. Painful erections and choree are the most common. They may be treated with tepid or cold applications, and by narcotics and refrigerants given internally. Antimonials may be prescribed with small doses of camphor, nitre, and henbane or opium; and a little extract of belladonna, or lint wet with the tincture of belladonna may be applied over the course of the urethra at bed time. Hemorrhage from the urethra often affords relief. If, however, it becomes excessive, it may be readily checked by cold applications, and by pressure. Inflammation of the mucous glands, or in the cellular tissue external to the urethra, may be poulticed; and if abscesses form, they should be opened early, or as soon as they obstruct the flow of urine. Swellings of the glands in the groin are generally removed by rest, and seldom require the application of leeches.

24. If Epididymitis, hernia humoralis, or swollen testicle, supravene, Mr. H. Coote believes "that the best plan is to strap the testicle at once, after the fashion represented in the work of Mr. Acton. A layer of collodion over the strapping is often useful. The relief thus afforded to the patient is surprising, and the swelling will often subside to one half in twenty-four hours. The application of cold, either by cold lotions or by the careful use of pounded ice and salt in a bladder, tends to relieve pain, subdue the inflammation, and reduce the swelling. When in consequence of pain this treatment cannot be carried out, we may fall back upon the practice of leeching the testicles, and of administering emetics. Nothing reduces inflammation of these organs more promptly than this, but the treatment is severe. When induration remains after the acute stage has passed, pressure is more serviceable than friction, whether of mercury or of iodine; both may, however, be employed." (H. Coote, Report, &c., p. 34.)—Since 1824, for the cases respecting which I have been consulted, I have ordered an emetic, afterwards an aperient, and the mixture (No. 374.) last prescribed; and, two or three days afterwards, full doses of the iodide of potassium in the above alkaline mixture (No. 378.). Iodine is rarely of use when employed externally in this disease.

25. d. In the third stage, or when the acute symptoms have subsided, the injections advised in the first stage may be discontinued; but if either of these occasions severe pain, their strength ought to be much reduced.

26. If the disease becomes chronic, and passes into gleet, a long-continued treatment is generally required to remove it, however judicious the means may be. The habits of the patient should be strictly regular and temperate, and pills made with venice turpentine, or with tar, or with copaiba and liquorice powder, may be employed. About thirty years ago I prescribed magnesia in the preparation of pills with these substances, but they became so hard after a short time as to be often passed from the bowels undissolved. If these fail, camphor, with sulphate of iron, or with sulphate of zinc, kina, or catechu, and small doses of cresate, may be taken in the form of pills; or the tincture of the muriate of iron, with the mixture of quassia or of calumba, may be given in any suitable vehicle. If micturation be frequent or painful, or if the urine deposits any mucin, the preparations of buchu, pareira, and uva ursi, are generally indicated. In most of these cases the cold salt-water douche, or local bath, sea-bathing, regular and generous living, suitable tonics, and chloroformic mineral waters, will be of essential service. If the disease still remain obinste, or if involuntary emissions occur, blisters to the perineum, the introduction of a bougie, or other means which fall within the province of the surgeon, may be employed.

27. e. The diet, regimen, and beverages of the patient during acute, subacute, and chronic gonorrea, should be strictly enforced. In the acute and subacute stages, constant repose on a cool sofa or bed, and on a hair mattress; a diet restricted to vegetable or farinaceous food in very moderate quantity; the careful avoidance of active exercise, more especially of exercise on horseback, and of heating beverages. The fluids taken should be cooling and demulcent. Weak black
VENEREAL DISEASES.—HISTORY OF SYPHILIS.

29. The first author who contended that syphilis was a variety of leprosy was M. Cumanus, in 1495. He considered it identical with the leprosy of Campania, described in the 13th century by Papa of Lombardy. A similar opinion was entertained by S. Aquilanus in 1497, by Campero, Lange, Bonghi, and Dodonaeus, early in the 16th century; and was supported by Zacutus Lusitanus, Maynwaring, and Musitarus in the following century.

30. That the distemper was brought from America by the followers of Columbus was asserted by several writers in the commencement of and early in the sixteenth century, especially by N. Poll, L. Schmausz, et U. Ad Huttten, and by many others. This opinion as to its origin was very ably supported by Astruc, and Gintanner (Abh. von der Lussteue, &c.) It was, however, denied by Sanchez (Abh. Uber der Ursprung Femneuse, &c., Bremen, 1775), who argued that an indigenous malady could hardly be brought to Europe and there become epidemic; by Salmiucito (loc. cit. i. p. 67); and by Hensler (Geschichte der Luessteue die zu Ende dis. 15. Jahrh. in Europa Ausbruch. Altona, 1769). More recently Desemuelles (Op. cit.) has contended for the introduction of this disease from America, and denied the importation of it from America. Despotes (Hist. de Malad. de St. Dominique, t. ii. p. 61.), Lagrange, Slogane, and numerous others; however, have shown, that a disease resembling syphilis was prevalent in Hispaniola when visited by the Spaniards, and was brought into Europe by them from 1493 to 1495. Astruc states that in the Neapolitan, or rather in the Spanish army, there were not a few of the soldiers who, returning from the Indies, either in the first voyage with Columbus, in the month of March, 1493, or in the second with A. de Torres, in the beginning of 1494, or in the third with P. de Margarit, at the end of the same year, were still infected with the venereal disease, or at least had contracted it in Spain, after it had been brought by others into Europe. And therefore it is by no means strange that many of the Neapolitans should be infected with the same distemper, as they served under the same colours, and conversed with the same females who followed the camp. Hence he concludes, that the disease was communicated from the Spaniards to the Neapolitans,—from both to the French,—and from all three to the other European nations, and to most of the people of Asia and Africa; though he believes that, under the torrid zone, there are some countries where it seems to have been a native and an endemical disease. (De Morbe Venereus, vol. ii. 4to. Paris, 1740, lib. i. cap. &c.) Sanchez de Ribero, in 1765, endeavored to establish that syphilis originated in Europe, and assumed the epidemic form in 1493. He was the first to shake the belief in the American origin of the malady, and was followed by Hensler, who believed it to have been intimately connected, in origin and nature, with the leprosy of antiquity, which he regarded as the precursor, in western Europe, of syphilis at the end of the 15th century. Richter (Chirurg. Biblioth. b. i. p. 163.), however, contends that syphilis was an ancient disease, and was imported into America by the Spaniards. But there is no sufficient evidence of such importation, by the Spaniards, whereas evidence is furnished by Arsenis.
VENEREAL DISEASES. — HISTORY OF SYPHILIS.

and others, that a similar distemper was prevalent in the West Indies and America amongst the natives when first visited by Columbus, and that they treated it with the same medicines as were found most successful subsequently by the Spaniards and Portuguese. That this distemper existed in America, in Western Africa, and probably also in other inter-tropical countries, before the discovery of America, appears to have been conclusively shown by numerous writers, although in more or less modified forms, according to race, mores of life, and numerous circumstances; and that it still exists in these forms, as a most prevalent and contagious distemper, in these countries, cannot be doubted. It was considered as being not improbable that the milder states of the disease prevalent in some of these countries, and in Hispaniola, when first visited by the Spaniards, assumed, in the latter, as well as in other Europeans, a much more severe character, especially when they became associated with scurvy, or with leprosy, then so prevalent in Europe, or with other epidemic or endemic diseases, or when the distemper first infected different races who had not been associated, could not in the same person, using different kinds of food, adopting different modes of living, and observing very different social and domestic habits, &c. That the disease is modified by these causes, by climate and by treatment, even at the present day, cannot be disputed, — and hence, most probably, it may have resulted from those distempers, which are denominated syphiloid by several writers, which are characterised by the most prominent features of constitutional syphilis, and which are different forms of syphilitic cachexia, arising out of those circumstances, in connexion with differences of race, with climate, habits of life, modes of communication, &c. (334. et seq.).

31. In addition to these opinions as to the history of syphilis, another had been from an early period entertained by several writers, but had received little attention until it was supported by D. C. G. GRUNER, who has inquired into the early history of syphilis (Moors) Romans ad portum Appian morati effecerunt, ut in continenter pestis invaserit urbem, mortuque sanct quam plurimi ex peste et contagione dicatorum Marranorum, de quibus tota urbs impleta est. GRUNER therefore infers from these and other authorities that the diseases to which the genitals were liable, owing either to impure connection or to leprosy or other causes, were developed into a pestiferous form by the distresses and other circumstances connected with the expulsion and emigration of the Moors and Jews, that the distemper in this malignant form was disseminated throughout Italy, — the French army invaded Italy in 1493, bringing it with them on their return to France, and that it spread rapidly from thence and from Italy to other countries.

* As it is manifest, in the present state of our knowledge, that syphilis is caused by a specific poison or contagious agent, originating, as far as we know, in the secretions of the sexual organs, and generally contaminate the disease by sexual intercourse, but sometimes also by contact under different circumstances, and in different stages of the malady, and even this much depends on the expectation that syphilis will not produce gonorrhoea, although both diseases are often associated; and that gonorrhoea will not give rise to syphilis, although like syphilis it is etiologically caused by sexual intercourse, but capable of being propagated by contact in other ways, so it has been thought that conclusions respecting the origin of the one disease cannot
VENEREAL DISEASES — History of Syphilis.

33. The question still remains unanswered as to the origin of the syphilitic disease brought by the Moors and Jews from Spain into Italy. It has been, as stated above (§§ 50–52), acknow-

ledged that the disease was introduced into Italy from Spain.
VENEREAL DISEASES.—HISTORY OF SYphilis.

Lived by many who have visited the West Indies and inter-tropical America, that a syphilitic disease has prevailed from time immemorial in these islands and countries; and writers soon after the discovery of America mentioned the communication of it to the Spaniards, who carried it back with them to Europe. 

Grenier states that at first he was inclined to believe this to have been the source from which it had been introduced into Europe; but, upon further investigating the history of the distemper, he was induced to relinquish this opinion in favour of the one he has espoused; but as to the question now at issue, he does not furnish a satisfactory answer further than that it was said by a few writers that the malady had long previously been introduced amongst the Spanish Moors from Africa, or brought from Africa by them. Now there can be no doubt that a syphilitic malady very similar to, or a slight modification only of the syphilis of modern times, was an endemic or indigenous disease in Africa long before the expulsion of the Moors from Spain, and most probably for many ages previously; and it is very probable that the disease existing amongst both Moors and Jews, even to a slight extent, may have been developed into its present magnitude and fatal state by the introduction by the circumstances connected with the emigration, and with the military invasion alluded to (§ 92.). I may refer the reader to what will be stated hereafter (§ 84. et seq.), respecting the diseases very closely related to syphilis, or syphilitic affections. There can be no doubt of these diseases having prevailed both in Africa and America long before the close of the fifteenth century; and admitting that they had been introduced into Europe by the followers of Columbus, they most probably had been brought into Spain by the Moors and Jews from Africa long before the discovery of America; and, existing among them, had been conveyed into Italy on their expulsion from Spain, shortly before the French invasion.

34. But admitting that syphilitic diseases (§ 92.) actually prevailed both in America and in Africa long before the discovery of Columbus, it does not follow that the disease brought by his followers from America was the same case of the epidemic syphilis of Italy and other countries in 1493, 4, and 5. Indeed this inference is completely disproved by facts; for, as Speenok has contended, syphilis, according to the testimony of most reputable authors, had appeared early in 1493, and soon afterwards extended to most of Europe, whilst, according to Oviedo, the most credible of all witnesses on the subject, the fleet of Gonsalvo, which conveyed the Spanish soldiers to Italy, arrived in Messina, on the 20th of May, 1495. Thus the disease was existing two years before the arrival of the Spaniards, and spreading in the army of Charles VIII. of France. That the disease existed in Barcelona in 1494 or 5, appears in a letter published by Tytius, from Nicholas Sculatius, a physician of Messina, the editor of an edition of the "Res Anglica," in 1497, and addressed to Aemarius Roxatus, physician to the Duke of Milan. From such a source as this it is evident that the disease was prevalent in the East Indies and other parts of the world, where the Spaniards had settled and introduced the disease. (See the chapter on syphilitic diseases, or affections closely allied to syphilis.)
VENereal Diseases. — Description of Primary Syphilis.

34. It is difficult if not impossible to determine accurately either the place or the date of the first appearance of syphilis in Europe. So rapidly did it manifest itself in one place after another, that it is impossible to determine the place in which it was first recognized. Fulgensius states that it appeared in Italy as early as 1492; Perrenius, C. Torella, Hachard, Ulich de Hutten, and Borgarutius, in 1493; John de Vico, Marva, Catenese, Hox, Schmaus, Fallopis, and many others, in 1494; Brasavolus, in 1495; Pherusius, Montesavurus, Mainard, Benivens, and Montanius in 1496; and Francastorius as early as 1490. It should not be overlooked that these and other authors evidently assigned the times without the disease became known to them, or in the places where they wrote, or they took the dates from the testimony of others. Wherever or whenever it first appeared, it cannot be disputed that it was speedily evinced in the chief cities of Europe. That it was seen as early as 1490, according to Francastorius, or 1492, as stated by Fulgensius, may be inferred from the circumstance of its having been mentioned, in the Mansfeld Chronicle, in the Leising Chronicle, the Legis Annals, and the Zweifelt Annals, as being general in Germany in the summer of 1493; and it is even said to have prevailed at least four years in Minskia. It was common in Avignone in 1493. It was known in Paris in 1494, and in Augsburg in 1495. It appeared in Memmingen, at Nuremberg, and in Edinburgh in 1496, and it spread through Bohemia in 1499. In few places, however, has it been so constant, so prominent, as in the cities of the Iberian peninsula not having been mentioned, insomuch as it had become there a well-known malady for ages before the end of the 15th century.

35. Description of Primary Syphilitic Ulcers. — These, usually termed chancre, are excised by the application of the syphilitic virus, to any part—mucous or cutaneous; to the former when entire or otherwise, to the latter also when entire, but much more readily when wounded or abraded. Their common seat is the genitals; in men, most frequently on the inner surface of the prepuce, or between the prepuce and coronal glandis, and especially in the angle by the side of the frarnum. "The time at which venereal sores appear, is said to be from the third to the tenth day after infection; but it is more probable, as Ricord observes, that the syphilitic virus operates progressively from the first moment of its application, but that the chancre is described in the letter, of an American origin.

36. Primary syphilitic ulcers present several varieties, which have been arranged by Mr. Henry Lee under the following heads: — 1st, The indurated or Hunterian chancre — a slow, torpid ulcer, encircled by adhesive inflammation; — 2d, The non-indurated, or pustulous, ulcer, marked by early and free suppuration; — 3d, The phagedenic or ulcerative; — and 4th, The sloughing; — 5th, To these I may add, Urethral chancre.

37. 1st. The indurated or Hunterian chancre "is generally found on the common integument, or on the glans penis. It may begin either as a pimple, or as a patch of excoriation which heals up, leaving the times without which this ulcer is produced by inoculation, in order to observe accurately its progress. M. Ricord states, that the puncture reddens during the first twenty-four hours; that in the second and third days it swells slightly, and becomes a pimple, surrounded by a red areola; from the third to the fourth day the cuticle is raised into a vesicle by a turbid fluid, with a black spot on its summit caused by the dried blood of the puncture; from the fourth to the fifth day, the morbid fluid increases, and becomes purulent, the vesicle becoming a pustule with a depressed summit. The areola, which had increased, now begins to fade; but the subjacent tissue becomes infiltrated and hardened with lymph." After the sixth day, "if the cuticle and the dried pus which adheres to it be removed, there is found an ulcer, resting on a hardened base; its depth equal to the whole thickness of the true skin, its edge wanting as if cleanly cut out by a punch—its surface covered with a greasy pustulous matter, and its margin hard, elevated, and of a reddish-brown or violet colour. The ulcer feels to the finger like a little cup of cartilage set in the flesh."
VENERAL DISEASES.—DESCRIPTION OF PRIMARY SYPHILIS.

40. 4th. Sloughing chancres are most frequently observed in the prepuce and integuments. Other chancres, however, presenting the simple states of inflammation observed in the second variety, may be changed into a gangrenous or sloughing state by local irritation, excessive horse-exercise, by excessive debauchery, intoxication, or whatever depresses or exhausts vital force.

41. 5th. Urethral chancres.—The secondary syphilitic symptoms which were formerly attributed to gonorrhcea have been satisfactorily proved by Record, but very long believed to proceed from a chancre in the urethra, and the distinct natures of the two venereal diseases thereby determined. The existence of chancre in the urethra may be inferred, if, with many of the symptoms of gonorrhcea, the discharge varies much, sometimes being thin, scanty, and bloody, sometimes thick and profuse; and if there be one painful and indurated spot, not far from the opening of the urethra. But the existence of urethral chancres can be certainly proved only by the ulcer being visible at the office, or by inoculation with the matter.

42. Syphilitic Ulcers in the Female may assume the several states described above. They do not commonly cause so much distress as in the male, although there are many exceptions to this rule; but they are always slow in healing, especially when the urine passes over or comes in contact with them. When they are seated high in the vagina, the symptoms produced by them are very equivocal, the discharge not materially differing from that attending other lesions; an excoriation by the finger or by the speculum being requisite.

43. iii. The Diagnosis of Primary Syphilis.—Various affections, described under their appropriate heads, may be mistaken for chancre. These are, 1st. Gonorrhcea externa, or balanitis, consisting of inflammation of the glans and inside of the prepuce, with profuse purulent discharge and excoriation of the cuticle. It may proceed from gonorrhcea infection, or from neglect of cleanliness, and the acid secretions of the part, or the unhealthy secretions of the female, especially in a person with a long prepuce; 2d. Minute syphilis, consisting of indurated papules; 3d. Herpes preputialis; 4th. Psoriasis preputii; 5th. Chronic eczema, which, however, rarely affects the genitals, unless it be present in other parts; 6th. Simple excoriations, from friction or other non-specific causes.

44. It must, however, be admitted, that the characters of primary syphilitic affections are not sufficient to enable us to distinguish them with certainty from the above or similar affections arising from ordinary causes; and that the several varieties of primary syphilis now described afford us no sure grounds for practical distinctions between each other. The only circumstance in which all writers, from Astuc to the present day, agree, is that ulcers of an obstinate nature, attended or followed by induration, are those most likely to be followed by constitutional disease. That the indurated chancres alone is characteristic of genuine syphilis, according to Hunter, Carr, these sores are never so irritable as phagedenic, being acutely painful, discharging a thin ichor, having a raised surface of yellowish exudation, but not spreading much although obstinately refusing to heal.

45. On this fundamental subject, Dr. Coles, a most experienced and enlightened surgeon, makes the following remarks: “Although every surgeon must admit that Mr. Hunter’s description of a chancre is correct, and drawn from nature, still, I believe the existence of this term, or that of primary venereal sore, to those ulcers only which answer to this description. As the result of long, attactive, and anxious observation, I should say that primary venereal ulcers present an almost endless variety of character. I would define a primary venereal ulcer to be one which is remarkably slow in yielding to ordinary, mild, local treatment; but which is curable by mercury, and which, if not so cured, is likely to be followed, in two or three months, by secondary symptoms, which again are curable by mercury. If, then, there be, as I affirm there is, an almost endless variety in chancres, how can we decide on the nature of primary ulcers, so as to pronounce some to be syphilitic, and others to be mere common sores, or simple excoriations? I reply, that we are to be guided in our decision by observing, first, that many of these suspicious ulcerations cannot be referred to any common ulcers, as they strikingly differ from them; and, secondly, by attending to the course which these take, when not interfered with by any stimulant or caustic application, and when treated only with some mild ointment or cold water. If, under these circumstances, we find that, after eight or ten days, such ulcers show no disposition to heal, and if at the same time there is a total absence of any cause, such as defect in the general health, to account for this obstinate condition of the local disease, we may then pronounce them to be syphilitic.” (Op. cit. p. 75.)

46. The constitutional effects of syphilitic infection are even still more variable and uncertain in their characters than the primary. It is manifest that bulb has been considered by many, and more especially by M. Boven, of too great importance, for it is certainly not a diagnostic of genuine syphilis, nor is it a secondary symptom, but merely a local consequence of the primary sore, —the effect of irritation, or of the virus conveyed, to the inguinal glands, by the abscesses from the local sore, no constitutional affection often supervening when it suppurates freely. When a patient has a syphilitic sore, which has not been destroyed within five days, he is liable
afterwards to these effects which will hereafter be described as secondary and tertiary syphilis. Yet, according to Mr. Henry Lee and Dr. Drury, it seems almost certain that it is chiefly after the Hunterian variety that these effects are to be dreaded, and their preventive treatment is required; and that there is a constant and slopping varieties, and those attended with suppurating buboes, do not, as a general rule, inflict secondary disease. A developed Hunterian chancre, or its cicatrix if hard or red, like the vaccine vesicle, affects the constitution, so that if it be not cured, the wound will assume the same character, and require the same constitutional treatment, as if the malady had not been interfered with.” It has also been recently shown that repeated syphilitic infection begets a protection against fresh attacks; and that the production of additional suppurating syphilitic sores not only does not confer any fresh liability to secondary symptoms, but seems to diminish that which exists already. Hence it has been proposed, as will be shown in the sequel, to inoculate syphilitic and other persons with syphilitic matter, or to syphilize them—in order to prevent and to cure this distemper—a subject which will be noticed under the part.

47. The marked differences presented by the primary sores and the secondary symptoms of syphilis, not only soon after the epidemic appearance of the distemper in Europe, but also during its subsequent prevalence, and in modern times, have been variously explained. Mr. Carmichael believed, that there were several distinct species of venereal poisons, each of which produced a specific primary sore and a specific train of secondary symptoms; that the Hunterian chancre, for example, was followed by an excavated ulcer of the tongue, scaly eruptions on the skin, nodes, &c. But the history of the malady, the diversified symptoms which result from either form of primary sore, and various other considerations warrant a belief only in one specific virus or poison, which manifests itself both primarily and constitutionally in varied forms, according to the circumstances and habits of the infected. Hence the primary morbid action, to the tissue with which the virus is brought in contact, and to the temperament, habit of body, diathesis, and susceptibility of the person infected. Hence arise different modifications or even varieties of the distemper—all resulting from one specific morbid poison. Thus they pass into each other in every phase or grade, without being originally or specifically distinct; and hence the one form or variety may prevail in different countries and races, and even in different ages, and under different influences, and yet give rise to another variety either as to form or intensity, when it infects different races, diatheses, and constitutions. Even in the same country and race, the circumstances and habits of the infected, especially mental and physical distress, prolonged fatigue and exhaustion, debauchery, frequent excesses and intoxication, neglect of health, cause a much more intense and intractable disease, than in persons differently circumstanced. It was most probably owing to these influences that the disease was so severe even in its primary symptoms amongst our troops during the campaigns in Portugal and Spain, and so mild among the natives.

Owing probably to the differences in race, it presented to my own observation in Africa, different modifications or forms and grades of intensity among the negroes, from those more usually observed in the white races. As to this topic, however, I would suggest a further, and more precise and extended notice, than I was enabled to make. There can be no doubt that in this country various forms of constitutional affection may proceed from the same kind of primary sore.

47* III. Syphilitic Bubo.—Inflamed and enlarged lymphatic glands, consequent upon a venereal ulcer, arise from the virus contained in, or secreted by this ulcer or chancre. This affection of the inguinal glands may arise from the irritation of, or absorption from, gonorrhoeal inflammation of the urethra; but it is not so frequent, nor so severe as when it is caused by chancre. Syphilitic bubo cannot be viewed as an indication of the existence, or even of the commencement of, the secondary or constitutional disease; for the affection of the glands may even, according to the more recent occurrences of the disease, be the means of preventing the constitutional contamination. This, however, was not the case in the earlier histories of the distemper, and more especially after the epidemic prevalences of the disease in the end of the 16th, and during the 17th century.—* The forms and diagnosis of bubo have been correctly and succinctly given as follows by Dr. Drury:—1st. Bubo of the penis is an inflammation of a lymphatic in the penis, which may be felt like a cord under the integuments, and which passes into abscess in some part of its course. 2d. Acute bubo in the groin generally affects one gland, and pursues the course of an acute abscess. The cellular tissue surrounding the gland is the usual seat of suppuration, but there may be also a small abscess in the centre of the gland, caused by the transmission of the poisonous matter, and the pus of this latter is alone capable of producing a chancre by inoculation. 3d. Chronic or indolent bubo commonly affects more than one gland. It occurs in weak constitutions; in our scrofulous habit and intensity of the primary morbid action, to the tissue with which the virus is brought in contact, and to the temperament, habit of body, diathesis, and susceptibility of the person infected. Hence arise different modifications or even varieties of the distemper—all resulting from one specific morbid poison. Thus they pass into each other in every phase or grade, without being originally or specifically distinct; and hence the one form or variety may prevail in different countries and races, and even in different ages, and under different influences, and yet give rise to another variety either as to form or intensity, when it infects different races, diatheses, and constitutions. Even in the same country and race, the circumstances and habits of the infected, especially mental and physical distress, prolonged fatigue and exhaustion, debauchery, frequent excesses and intoxication, neglect of health, cause a much more intense and intractable disease, than in persons differently circumstanced. It was most probably owing to these influences that the disease was so severe even in its primary symptoms amongst our troops during the campaigns in Portugal and Spain, and so mild among the natives.
tic unless preceded by chancre, unless a chancre can be produced by inoculation of the discharge, or unless decided secondary symptoms supervene.

49. IV. SECONDARY SYPHILIS. — Constitutional syphilis may occur from a fortnight to three or four months after the primary symptoms. The usual time is five or six or seven weeks. Early in the history of syphilis in Europe, the constitutional affection was much more early than the shortest time now named, and was not infrequently the first produced owing to the readiness with which the contagious principle was imparted and imbibed. Before the appearance of secondary symptoms, the constitution betrays its infection by a variety of premonitory symptoms,—by a dispirited and even wan expression, by want of appetite and sleep; by heaviness of the eyes, rheumatic pains, especially during the night, and pallor and loss of flesh; and lastly, by a slight eruption fever usually of an inflammatory type. Upon these, after a short but variable period, the secondary symptoms supervene, some throat generally accompanying this fever or soon following it.

50. The symptoms premonitory of the secondary or constitutional disease are sufficient evidence of the infection of the body by the primary disease, although those alterations usually termed secondary are not yet developed. The dull, earthy hue of the surface, the loss of bodily and mental vigour; the dryness of the hair, and loss of its smoothness and glossiness, and the giddiness, headache, uneasiness about the neck, or supraorbital pain, usually on one side, and when the body is recumbent, are amongst the earliest indications of this infection. On these supervene pains about the joints; lassitude of the limbs; enlargement of the posterior cervical glands; loss of the tone, fullness and strength of the pulse; more or less anaemia, and falling out of the hair. The loss of hair indicates an inactivated form of disease, and is often attributed by patients to the use of mercury; but this mineral will not cause alopecia, but syphilis, Dr. Durrer's opinion, more properly belongs to the class of tertiary symptoms, in which mercury is almost inadmissible. This eruption usually appears a very considerable time from the primary symptoms in persons of weak constitution, or who have been broken down by privation, dissipation, or unavailing courses of mercury; it is consequently an unfavourable form of the disease. "A patch of this kind of unhealthy inflammation is apt to form on the tongue, and after a time an abscess breaks, disclosing a ragged excavation, filled with orange-coloured sloughs, and exuding a copious fetid discharge. If it occur on the palate, a probe will detect bare exfoliated bone, which rapidly perishes, and leaves a hideous cleft."
such a result may follow the tubercular or even the pustular forms of secondary syphilis in certain favourable circumstances. (The several forms of syphilitic eruption are more fully described in the several articles devoted to diseases of the skin.)

56. Venereal eruptions are not severally characteristic of any distinct form of syphilis, primary or constitutional. Dr. COLLIER states that he has not been able to trace back particular forms of eruption, to particular forms of primary ulcer. 2d. He has not unfrequently observed varieties of eruption existing together in the same person. 3d. After the removal of the first eruption by mercury or other means, the second crop will often prove of a different kind; and 4th. any form of eruption may be converted, by injudicious treatment, as the excessive use of mercury in bad habits, into one which is most obstatine and severe. This opinion agrees with those of HENSEN, OESEREBE, & COOPER, BACOR, and others. Mr. BACOR says, "The eruptions of venereal eruptions are so great as to disable description. He, however, arranges the more distinct forms under the heads of Tuberaca, Lichem, Pustules and Lepres, and Rupia. The most important practical point, which many writers connect with these distinct forms of venereal eruptions, is, that rupia and eczema are met with in a very dangerous general depression of health, requiring the greatest care.

57. The diagnosis of secondary syphilis is of great importance — is sometimes very easy, and occasionally very difficult. In all cases the previous history of the patient should be inquired into. It is not only necessary to ascertain whether or not a chancre has existed, but also the time when it occurred, its situation, and its character. If no chancre, but gonorrhœa only, in male or female, preceded the eruptions, it should be recollected that chancre may have escaped the patient's notice, or may have existed in the urethra of the male, or in the vagina or cervix uteri. In these cases, caution and further observation are required, if sores are admitted, their characters, especially as regards induration, are of importance. A knowledge, likewise, of the existence of suppurating bubo may be useful, for indurated chancre is rarely detected by suppurating swelling in the groin; and lastly, the existence of any traces of

indurated chancre or bubo ought to be ascertained, the denial of the patient not being sufficient.

58. As respects the eruption, M. RICORD remarks that one of the most important characters of it is a total absence of pruritus, whereas itching is a very frequent symptom of the other kinds of eruption. When, however, the syphilitic eruption affects natural parts, — i.e., that in the anus, genito-crural fold, there may be considerable itching owing to the irritating nature of the secretion. Syphilitic eruptions are generally apyretic and indolent, involving in a short time the whole body, generally by successive instalments. They spread indiscriminately to all parts, and do not affect the face in preference to other parts. They emit no smell, unless there be an exudation of fluid or suppuration. "There is nothing specific in the smell, nor in the colour mentioned by Smeubers, nor the ham-like hue spoken of by Falloppius, which latter has been, with reason, looked upon as an important sign, and an ancient and constant character." Secondary eruptions generally present rounded and well-defined patches, the colour of which may be more or less deep in their centres. They have very little tendency to suppuration; and when matter does form, it is generally small in quantity, and unhealthy in character. The eruptions which do not suppurate, generally disappear in time by resolution or desquamation. The scales in these cases are less brilliant and thinner, dry more quickly, and more frequently furaceous than in non-specific affections, and the scales sometimes fall off in large scale-like pieces. The eriis sometimes accumulate in successive layers as in rupia. When, by the falling of the crust, the ulceration underneath becomes apparent, it generally is rounded, its fundus greyish and palpeceous, is surrounded by a darkish areola, with a certain induration in the margins. Phagedena of these ulcerations is rare; but when it does happen, it sometimes extends rapidly. Secondary syphilitic ulcers are preceded either by some eruption, as eczema, rupia, papular, or tubercles; they rarely follow vesicles or pendraneous pustules. Ricord agrees with Huxman in considering the diagnosis of secondary syphilis established by the fact that it is hardly any disorder that has more diseases resembling it in all its forms than the venereal disease."

59. G. Secondary affection of the scalp — Alopecia syphilitica is amongst the earliest constitutional disorders consequent upon syphilis. It commences with slight itching, tenderness or soreness of the scalp, attended by rheumatic pains. On examination, no trace of eruption can be detected; but if the patient have suffered within four or eight weeks, from chancre, or if any induration remain in its situation, the tenderness of the scalp will soon be followed by broken-off hair and some one of the affections of the skin, throat, &c. The alopecia commences very gradually. The hair at first becomes dry and crisp, loses its glossy appearance, breaks readily, a brush or comb causing great pain. The hair is often seen broken off at the scalp, and patches of baldness, or approaching to it, are found here and there. At a more advanced stage the hair comes away with the bulbs in considerable quantity. Pityriasis now becomes troublesome; and various points of the scalp..."
venereal diseases—secondary syphilis.

Rosy hue; the rest of the skin generally having a yellowish, unhealthy appearance. Slight febrile symptoms set in, attended often with rose-coloured spots on the abdomen. The patient now frequently complains of rheumatic pains in the joints, with loss of motion and stiffness. The loss of hair requires immediate attention, especially when caused by syphilis, as it may be very considerable in a short time, and its growth very uncertain. It should, however, be remarked that if the hair does not fall out at the commencement, it is not very frequently lost in the latter stages of constitutional syphilis.

60. At a more advanced stage, a papular affection of the scalp, commencing with little rose-coloured elevations, attended by itching, is observed. These papule, or lichen, increase in number, slight pearly-white scales form on their apices, which fall away and are replaced by others. The hair is scanty, and the papule or elevations, at first the size of millet seeds, become large and assume the form of lepra or psoriasis. When the scales are removed, the skin looks like a recently-blistered surface, and exudes a small quantity of this pellucid fluid; or it is quite dry. In particular situations, especially behind the ears, in the folds of the neck of stout persons, or those insensitive to cleanliness, these places instead of becoming scaly remain moist, the oozing from them excoriating the surrounding parts, and developing mucous tubercle or condyloma. As the disease of the scalp advances the papule or lichen pass into an impetiginous or an eczematicous state. In still more advanced stages, ulcerations of a very intractable character, forming tertiary symptoms, form in the spots of impetigo or eczema; and tumours as large as horse-beans form in the scalp, at first unattended by pain or redness. Fluctuation may be detected in them after some time, and when punctured a thin, serous, straw-coloured fluid exudes. If left alone they become painful and red, ulcerate, exposure of the bone ultimately following, and even necrosis, which are now chiefly seen in pathological collections, and not usually of late date, the necrosis, and afterwards produce exfoliation of the bones and profuse fistulous discharge, and ultimately very marked deformity. Ulceration of the nose generally begins with ozema, or with a sense of pain, heat, dryness, and swelling. But the bone of the nose may become otherwise attacked, as shown in the sequel (§ 75).

61. H. Syphilitic Oxychoia.—The venereal affections of the skin or scalp may be extended to the nails. In these cases the matrix suffers, and the nail grows thick and nodulated, closely resembling the changes which take place in it in invertebrate psoriasis. There is a great similarity between oxychia and alopecia. They both depend upon the constitutional infection interfering with the formation or nutrition of these cuticular appendages.

62. ii. Syphilitic Affections of Mucous Surfaces.—A. Syphilitic Affections of the Throat. —a. The mildest affection of this kind is a superficial exoriation of the mucous membrane, most frequently of the tonsils, but not uncommonly also of some other parts of the faucets or mouth, corresponding to psoriasis on the skin. The affected parts are slightly swollen and sore, afterwards red and raw, with loss of defences and ability. The loss of hair requires immediate attention, especially when caused by syphilis, as it may be very considerable in a short time, and its growth very uncertain. It should, however, be remarked that if the hair does not fall out at the commencement, it is not very frequently lost in the latter stages of constitutional syphilis.

63. b. An excoriated ulcer may follow the foregoing, or may be first to come before the physician, although it may have been a consecutive lesion of the parts. This ulcer appears as if a piece had been scooped out of the tonsil. Its surface is foul or yellow, its edges raised and ragged, and swollen. It occasions much less inconvenience than its appearance might indicate; and there is very little constitutional disturbance consequent upon it, unless it is complicated by eruption. As the ulcer advances, or swelling increases, the patient's speech becomes guttural, and he often complains of pain shooting to the ears, and of partial deafness.

64. c. Slaughtering ulcer begins as a small elliptical spot which rapidly ulcerates, and is attended with great pain and fever. "The surface of the ulcer is covered with an ashy slough, and the surrounding membrane is dark, livid, and swollen. The lingual artery may be opened by the spread of the ulceration, and the patient may die of hemorrhage, unless the common carotid is tied." (Dewitt, p. 197.) In some instances, especially when mercury has been given in large quantities for primary symptoms, the affection of the throat comes on notwithstanding, and assumes a red and sloughy appearance; a piece of the tonsil appears as if punched out, and the ulcer rapidly extends in size and extent.

65. The situations of the ulcerations, most frequently of the excavated, is commonly on the tonsils, on the sides of the tongue, on the upper surface, or on the under surface close to the frenulum. Sometimes they are met with on the dorsum of the tongue, here assuming an elevated character, like the condylomata around the same. They occasionally attack the palate, pharynx, and more rarely, in the posterior and lower part of the pharynx, in which latter situation it occurred in a patient many years ago under my care, ulcerating also having extended to the larynx and terminated fatally. Ulcers also form at the corners of the mouth, where they may form scars, or are liable to bleed, when the mouth is fully opened.

66. B. Syphilitic ulcerations of the nose and palate commence with inflammation and ulceration of the mucous membrane covering the parts, similar to those of the throat. The ulcerations may proceed until the present day, the necrotic exoriation, and afterwards produce exfoliation of the bones and profuse fistulous discharge, and ultimately very marked deformity. Ulceration of the nose generally begins with ozema, or with a sense of pain, heat, dryness, and swelling. But the bones of the nose may become otherwise attacked, as shown in the sequel (§ 75).

67. C. Syphilitic ulceration of the larynx is chiefly a consequence of the extension of ulceration from the palate or pharynx. It is characterised by tenderness, slight pain or uneasiness referred to the larynx, by huskiness of voice, followed by a low whispering, or loss of voice; by suffocative cough, and by expectoration of a sanguineo-puriform matter. There is great less of strength and flesh; and life is often terminated by suffocation.

68. D. Secondary affections of the eye-lids and eyes. —Not only with inflammation, but by the ulcerations or eruptions be consequent upon gonorhea (see art. Exts. Gonorheal inflammations of, § 56, et seq.), but eruptions and affections of the eye-lids and of the eyes themselves, chiefly in the form of iritis, may appear in the course of secondary or constitutional syphilis. These eruptions often appear on the external surface and on the ciliary margins of the
lids. In some instances, the corners of the eyelids have a cracked, scaly appearance, resembling a similar alteration more frequently occurring at the angles of the mouth, and, as in this latter state, the eruption is connected with syphilitic affections of either the skin or of the mucous membrane, of the throat, &c., or of both; and it may appear in any period of the process of these affections. In some cases, the conjunctiva is also either partially or extensively implicated. *Syphilitic iritis* is not uncommon; and is fully considered in the article on the diseases of the eye (§ 132, et seq.), to which I must refer the reader.

69. III. TERQARY SYPHILIS. DISEASES.

Certain constitutional effects of syphilis, which more frequently are consequent of several of those already mentioned, than associated with them,—although such associations, especially in the advanced course of the latter is often observed—have been classed as tertiary symptoms of the disease. They may, however, occur many years after the removal of the secondary forms of the distemper, or independently of these, and at a remote period from the primary symptoms. Under the term tertiary symptoms have been arranged nodules, inflammation of the periosteum, exostosis, caries of the bone, tubercles of the subcutaneous and submucoous tissues, disease of the testes consequent upon primary or secondary syphilitic disease. These affections were generally classed with those secondary symptoms already noticed. John Hunter first distinguished them by designating them the "Symptoms of the second period of constitutional syphilis," a designation which many will agree with me in considering as more appropriate than that imposed on them by M. Ricq. No. 70. Though tertiary symptoms generally depend upon chancre, or, in rare cases, upon infection by a secondary disease, they follow the primary symptoms after a much longer interval, and are seated in other and more deep-seated structures than the secondary. They affect chiefly the sub-mucous and sub-cutaneous cellular tissue; the structure of the bones; the fibrous structures, especially the periosteum; the joints; the testes, and lymphatic system. The syphilis of bone and joint may cause death of the liver, lungs, brain, and heart. Tertiary affections cannot be transmitted from parent to child—are not hereditary; but they are undoubtedly capable of producing a hereditary diathesis in the offspring. No. 71. A. Course. In the more usual course of the disease, tertiary symptoms do not supervene until six, seven, or nine months from the primary, and in some they may be delayed for several, or even as many years. Although these symptoms may be separated with propriety from the secondary, yet it will very frequently be difficult to draw the line of demarcation between them. They may be both so associated, or the one class may pass so insensibly into the other as not to admit of an inference as to the predominance of the one set of symptoms over the other. In the natural course of syphilis the tertiary form very frequently takes place during the presence of the secondary, in the same way as the latter may come on during that of the primary. Under other circumstances, as from treatment, careful regimen, &c., the secondary symptoms may have successfully disappeared and returned, and ultimately the tertiary have supervened; and even, although in rare instances, an indurated chancre may have existed, and been apparently cured, yet, after a very considerable lapse of time, tertiary symptoms may appear generally from the influence of causes hereafter to be noticed (§ 109, et seq.), at first in a slight form, but with increasing severity, notwithstanding the non-existence of secondary symptoms between the primary and tertiary. During the course of tertiary affections, various complications may be developed, not only by the syphilitic poison, but also aided by treatment, by pre-existing tendency to visceral or other diseases; by the causes, influences, and circumstances to which the patient may have been exposed, and by climate, race, occupation, &c.

72. B. Syphilitic affections of the testes are generally amongst the earliest of tertiary symptoms to appear, and may occur during the existence of the secondary. They may, however, supervene in five or six months after the removal of the secondary forms of the distemper, or independently of these, and at a remote period from the primary symptoms. Under the term tertiary symptoms have been arranged nodules, inflammation of the periosteum, exostosis, caries of the bone, tubercles of the subcutaneous and submucous tissues, disease of the testes consequent upon primary or secondary syphilitic disease. These affections were generally classed with those secondary symptoms already noticed. John Hunter first distinguished them by designating them the "Symptoms of the second period of constitutional syphilis," a designation which many will agree with me in considering as more appropriate than that imposed on them by M. Ricq. No. 70. Though tertiary symptoms generally depend upon chancre, or, in rare cases, upon infection by a secondary disease, they follow the primary symptoms after a much longer interval, and are seated in other and more deep-seated structures than the secondary. They affect chiefly the sub-mucous and sub-cutaneous cellular tissue; the structure of the bones; the fibrous structures, especially the periosteum; the joints; the testes, and lymphatic system. The syphilis of bone and joint may cause death of the liver, lungs, brain, and heart. Tertiary affections cannot be transmitted from parent to child—are not hereditary; but they are undoubtedly capable of producing a hereditary diathesis in the offspring. No. 71. A. Course. In the more usual course of the disease, tertiary symptoms do not supervene until six, seven, or nine months from the primary, and in some they may be delayed for several, or even as many years. Although these symptoms may be separated with propriety from the secondary, yet it will very frequently be difficult to draw the line of demarcation between them. They may be both so associated, or the one class may pass so insensibly into the other as not to admit of an inference as to the predominance of the one set of symptoms over the other. In the natural course of syphilis the tertiary form very frequently takes place during the presence of the secondary, in the same way as the latter may come on during that of the primary. Under other circumstances, as from treatment, careful regimen, &c., the secondary symptoms may have successfully disappeared and returned, and ultimately the tertiary have supervened; and even, although in rare instances, an indurated chancre may have existed, and been apparently cured, yet, after a very considerable lapse of time, tertiary symptoms may appear generally from the influence of causes hereafter to be noticed (§ 109, et seq.), at first in a slight form, but with increasing severity, notwithstanding the non-existence of secondary symptoms between the primary and tertiary. During the course of tertiary affections, various complications may be developed, not only by the syphilitic poison, but also aided by treatment, by pre-existing tendency to visceral or other diseases; by the causes, influences, and circumstances to which the patient may have been exposed, and by climate, race, occupation, &c. No. 73. C. Small Tumours are sometimes formed in the scrotum, and are described as tubercles, or gummatæ, either in connection with disease of the testes or independently of it. They occur as a tertiary symptom in the deep layers of the scrotum, and sometimes implicate the testes, or are mistaken for affections of these organs. They never appear before the fifth or sixth month from infection; but they may occur after many years. They mostly appear as small elastic tumours, and feel as if they were filled with a gummy matter. As they grow they become painful, inflamed, and the skin covering them softens and ulcerates, and a deep ulcer follows a copious purulent discharge. The edges atrophy and become lined, and the adjoining parts are involved in the destruction. No. 74. D. Syphilitic disease of the periosteum and bones, generally commences with tenderness in the situation of the more exposed and superficial parts.
especially in the bones of the nose, in the tibia, ulna, cranial bones, clavicles, &c. The tenderness and pain become aggravated in the evening, last all night, but cease altogether or abate during the day. The pain is followed by oblong swellings or nodules, which may appear either on the periosteum, and by the infiltration of lymph and serum. These swellings are tender, and the skin over them is at first pale and moveable. They present to the touch a doughy character, or an obscure sense of fluctuation. Dr. Druitt remarks that, "if the disease is arrested at this stage, it causes merely a superficial deposit of rough porous bone, from the organisation of the lymph effused; or else consolidation of the bone itself, through deposition of fresh ossous matter into its cancelli. If the disease proceed one step further a quantity of glairy serum is effused between the periosteum and bone, producing an exquisitely painful fluctuating tumour. If it advance still further, the bone becomes carious; matter forms between it and the periosteum; extensive exfoliations ensue; the patient suffers severely from the pain and discharge;" and if the disease be seated in the tibia or os frontis — the latter is the most common — it may advance from extension of disease to the drum mater, or from protrusion of the brain through the eroded apertures in the skull. Such extreme cases are now very rare, but they were common enough many years ago, and when it was supposed that mercury given in excess was the only cure for the distemper.

75. D. Disease of the bones of the nose is often amongst the earliest of the tertiary symptoms, but it is of only occasional occurrence, and sometimes not until an advanced period. The nose may become diseased, as stated above (§ 66.), from ulceration of the mucous membrane, but the formation of internal nodules on the palate, vomer, ethmoid, and bones forming the bridge of the nose, may cause these bones to be carious, and probably the spongy structure of these bones may contribute to this even so quickly as it is sometimes observed. In rare cases these bones are nearly destroyed before the nature of the disease becomes apparent. When caries of the os frontis near the root of the nose takes place the disease may extend to the ethmoid bone, and produce the worst effects. The existence of a deep-seated pain in the palate, and at or near the root of the nose, with or without a foetid discharge, should always be viewed with suspicion, especially if either primary or secondary symptoms have existed at some previous period, although very remote, and apparently altogether removed. Ozema may proceed from seborrhoea, seury, or even from chronic ophthalmic catarrh; but in nine cases out of 100 it is the result of syphilis in the circumstances just named.

76. F. The joints are not frequently nor so quickly affected as the bones. Large gummy swellings sometimes, however, form around the ankle, knee, and elbow joints, owing to venereal disease, and in rare cases to the joints themselves. In two instances I was consulted where nearly all these joints were remarkably swollen and diseased, consequently upon other serious syphilitic affections. In a third — that of a late M.P. — amputation of the leg above the knee had been performed by Mr. Dalrymple of Norwich, and the case subsequently came under my care.

The small bones of the extremities may also be similarly affected. In venereal diseases of the joints it is difficult to determine, as I have not seen these cases terminate fatally, although they doubtless occasionally do, whether the disease is entirely external or by infiltration of the periosteum, and by the infiltration of lymph and serum. These swellings are tender, and the skin over them is at first pale and moveable. They present to the touch a doughy character, or an obscure sense of fluctuation. Dr. Druitt remarks that, "if the disease is arrested at this stage, it causes merely a superficial deposit of rough porous bone, from the organisation of the lymph effused; or else consolidation of the bone itself, through deposition of fresh ossous matter into its cancelli. If the disease proceed one step further a quantity of glairy serum is effused between the periosteum and bone, producing an exquisitely painful fluctuating tumour. If it advance still further, the bone becomes carious; matter forms between it and the periosteum; extensive exfoliations ensue; the patient suffers severely from the pain and discharge;" and if the disease be seated in the tibia or os frontis — the latter is the most common — it may advance from extension of disease to the drum mater, or from protrusion of the brain through the eroded apertures in the skull. Such extreme cases are now very rare, but they were common enough many years ago, and when it was supposed that mercury given in excess was the only cure for the distemper.

77. iv. The Syphilitic Cachexia. — It may justly be asked, can syphilis so contaminate the constitution as to give rise to dangerous or even fatal results of a different kind, or in addition to those which have been described above as secondary and tertiary? To this question I cannot hesitate to answer, but merely to state that the results do not often occur in the present day; and even the most severe of the tertiary affections noticed above, although sometimes terminating fatally, have not always this issue. In their most unfavourable results, it is often difficult to say how much may be imputed to treatment. But, irrespective of the more severe and dangerous of the affections already mentioned, states of the system may be induced, attended by marked severity or imminent danger, in which none of these affections had appeared, or, if they have appeared, at some previous periods they had been removed by medical treatment or regimen. This dangerous state of constitution — this the most remote or advanced of the effects of the syphilitic poison — has not been overlooked by previous writers, more especially by Dr. Colles and Mr. Ricord.

78. Syphilitic cachexia is generally a consequence of a single constitutional contamination — such contamination not occurring twice — and is favoured by the following circumstances: — 1st, by an originally weak or bad constitution, by seborrhoea, seury, and a peculiar or vitiated diathesis, previously to the venereal infection; — 2d, by the persistence of certain severe syphilitic symptoms; — 3d, by an ill-timed or badly managed treatment, and by neglect of treatment; and 4th, by causes which tend to lower the vital powers subsequently to infection, — such causes, according to my observation, being excessive sexual indulgences, masturbation, exposure to cold and moisture, to the continued influence of malaria, or to noxious excitations, &c.
VENEREAL DISEASES — Syphilis in Children.

80. Sometimes, after the patient has improved, under treatment for various secondary or tertiary symptoms, in respect of both of these symptoms, and of flesh, strength and appearance, he begins to exhibit a much less favourable aspect. He appears sickly, loses flesh, presents a wan hue, complains of loss of appetite and strength, of want of sleep and of night sweats. If any eruptions or other syphilitic symptoms are present, they may disappear, and yet the general constitutional cachexia may long remain, or even become more marked; or, if the local symptoms continue, they may be slowly deteriorated. Thus tuberculous eruptions, or pains in the joints and bones may continue in various grades of severity for some years, whilst the constitution is slowly wasted, anaemic and visibly contaminated. In some cases the local symptoms, in the course of the general breaking down of the frame, are so changed as hardly to be recognized as venereal,—various local or visceral changes, the consequence chiefly of cachexia, or of the treatment, being developed, and masking the venereal affection and its effects. This formerly obtained more remarkably when the treatment by mercury was carried to excess. There can be no doubt, however, that, even independently of this, or of any other treatment, the venereal cachexia may terminate fatally by calling latent tendencies into action, and by developing disease in vital or other internal organs. It may, however, be most manifest in all its indications, even when the local affections are comparatively slight; or, although they have been severe, after they have entirely or almost altogether disappeared. The local affections, as well as the constitutional contamination are often developed, hastened, delayed, or aggravated by a number of circumstances, influences, and concomitants, if (§ 115. et seq.), to which the patient may have been exposed subsequently to the period of infection. During syphilitic hectic or cachexia, not only may the consequences now alluded to appear, but there are several others which may also supervene; namely, paralysis, epilepsy, hypochondriasis, melancholia, monomania, and even more or less general insanity. These disorders of the mind are, however, seldom met with in the most advanced states of constitutional syphilis—the intellect being generally but little, or not at all, affected to the last.

81. The Diagnosis of constitutional syphilis is often very difficult, more especially when patients deny that they have had any primary symptoms, or even any suspicious intercourse, or even any sexual intercourse whatever. These last circumstances are, however, very rare, or may even be considerably mitigated in favourable cases. But the rare modes of communicating the distemper, independently of sexual connection,—much more common in former times than now,—should not be forgotten. These modes will be noticed in the sequel (§ 110. et seq.). If, however, copper-coloured eruptions, sore throat, loss of hair, enlargement of the glands around the occiput, pains in the joints, peristomeum or bones, peristomial nodes on the long and superficial bones, with night pains, a faded, pallid, or waxen and unhealthy look, loss of flesh and strength, be complained of; and more especially if these symptoms follow a somewhat similar succession, and cannot be attributed to locality, diet, regimen, &c., or to any recognized visceral disease, they may be confidently referred to constitutional syphilis. Where, however, neither the above succession of symptoms, nor many of them, appear, the difficulty of diagnosis will be much greater, especially if primary symptoms be not admitted; but, if admitted, there can be no doubt of the nature of the disease, although a long period between the existence of the primary symptoms and the appearance of those which are doubtfully secondary may have intervened. It has been stated above, that the period to which the superposition of secondary and tertiary symptoms upon the primary may extend may be very long—may even extend to several years; but the exact term to which this interval may be extended has not been ascertained. Its duration evidently depends upon a variety of causes and circumstances (§ 115. et seq.).

82. vi. SYPHILIS IN INFANTS. — Syphilis Infantum. — Hereditary Syphilis differs so far from the disease as it occurs in adults, as to induce some writers to doubt its venereal origin. It is certainly the transmission of the constitutional contamination or distemper to the fetus, during utero-gestation, and not the infection of the fetus during parturition. The malady may exist at birth, or may not appear for some days or even weeks after birth. It is indicated by copper-coloured spots on the cutaneous surface, especially about the arms, genitae, and mouth, which may go on to ulceration. There are also a peculiar shrill or hoarse voice, evacuations and ulcerations, or an aphthous appearance, at the corners of the mouth, on the tongue, throat, and palate. In more advanced stages, en Characters and a senile appearance of the countenance; snuffling, or obstruction of the nose, enlargement of the glands, general cachexia, terminating in death, if the disease be not early detected and judiciously treated, and even in such favourable circumstances the child may be carried off by some severe complication. In most of the cases of syphilis infantum, the mother has been stated to have infected the fetus. I believe, however, that the infection has not always proceeded from the mother only. Schenck adduces an instance (Observ. le vj. nov. 21.) of the infection of the fetus from the father, the mother being unaffected. It must, however, be admitted that it is very difficult to prove the mother to have been untaught by the distemper, when the father has been affected. Upon the whole it may be generally expected that the fetus will manifest the disease when the pregnant mother is constitutionally affected; and it is not improbable that the child may be infected by a constitutionally syphilitic father, without the mother having been uninfected. But the rarest symptoms of the constitutional or primary distemper. MAURICEAN, however, has adduced instances of the child having been free from syphilitic taint, although the mother was affected; and I know cases of the children being free. [Note: AQ&A]
festy owing to the parts primarily infected and affected, and to the progress the distemper had made when arrested by treatment. The disease was often fatal in children and infants in whom it had made progress before submitted to treatment. Dr. Bowmen, in an account of the disease in the West Indies, says that the disease is prevalent between the years 1776 and 1780, not only in this locality, but also in some other parts of Canada. It was described by Dr. Bowman, who was ordered by the Governor to investigate the disease, and after examining it, he ascertained that the disease was most frequently the disease commenced with aphthous ulcers on the lips, tongue, and inside of the mouth. These advanced rapidly, and the tongue, palate, &c., were sometimes nearly destroyed by them. The whitish purpuric matter exuded from them communicated to the skin of others. Older patients complained of pains in the bones, and of slight febrile exacerbations, until eruptions followed by ulcers appeared on the skin, and in the mouth and throat, when the pain abated. These ulcers, according to their situation, which depended upon the contact of the virus, were followed in many instances by cervical, axillary, or inguinal buboes. At a more advanced stage the body became covered with purpuric ulcers, which soon disappeared. The ulcers of the nose, palate, cranium, pelvis, and extremities, were ultimately attacked by nodes, and eventually disappeared. The ulcers appeared together and contiguously, and many sunk in a state of extreme wretchedness, especially children, the weak, and neglected. Robust persons withstood the successive complications of the disease for many years.

95. The inhabitants of the parts where the disease appeared, stated that it was introduced and extended by sexual intercourse, by contact, and by foul clothing. It spared no one exposed to infection, but was most virulent in children. Swineherds, admitting the imperfections of the description given of the distemper by Dr. Bowman, considered that it agreed with the earliest accounts of syphilis in the 16th and 17th centuries. It is also manifestly the same malady as that which was epidemic in 1800, and in following years until 1809, in districts of Soberiato, Gremiosanto, Fiume, &c.

96. The Syphilis of Schereliev, or the epidemic which received this name from its occurrence in this locality. M. Parry and Laveron, state that, in this district and those adjoining it, the commission appointed to inquire into the nature of the distemper, found more than 13,000 persons infected by it, out of a population of 30,000. It reappeared, or became epidemic again, in 1808 and 1809, where it seemed to have been perpetuated by the filth of the lower orders, whose damp cabins were shared with their domestic animals. The disease usually commenced with ulceration of the limbs and pains in the bones, which increased during the night. The voice becomes hoarse, deglutition difficult, and the extremities of the long bones, attended by caries, softening, exostosis, &c. This state of the disease, called bone-evil, is often attended by the formation of numerous ulcers, by affection of the bones of the face, of the palate, &c.; the patient often being reduced to a horrible state. The chief difference between yaws, pim, and syphilis, in its aggravated state of secondary disease, is in the fungiform aspect of the ulcers in yaws and pim; but this state of the eruption in these affections (Frangipanes) is probably to be imputed to the peculiar nature of the body, with hard or thick hair, and color of the Negro, in whom this distemper was observed by those who have described it. The following accounts of the occurrence of syphilis as local epidemics are interesting, inasmuch as they exactly agree with the descriptions given of syphilis in the 15th and 16th centuries.
and nodes in rare cases vanished along with the pains, as soon as a purpuric eruption was evolved on the skin.

97. In many cases, after the pains in the bones, a purpuric eruption appeared on the surface, which M. Bovis states to have been announced by a secretion which disappeared when the eruption was fully out. The purpurs were of a coppery colour, round, and of various extent; and appeared most frequently on the forehead and hairy scalp, on the inner surface of the thighs and extremities, and around the anus and genitals. In some cases an acrid itch exuded from them, which excoriated the skin; in others the discharge dried and formed scabs. The disease often remained stationary in this state for a long time. After the scabs had fallen off, the skin retained marks of a coppery hue, which were removed with difficulty.*

98. The disease appeared in some cases with various sized blotches of a coppery colour, in the centres of which ulcers were formed, from which a matter was exuded which formed scabs similar to those which covered the purpures. These blotches were surrounded by a coppery areola. It was remarked that the female genitals were more frequently affected than the male.

Dr. Camberwell, among an immense number of cases, found only one of gonorrhea, which complicated the distemper. The ulcers which often eroded the scrotum were consequent upon the general infection. Buboes in the groins, or enlargements of other lymphatic glands, were seldom seen. The modes of communicating the malady were the same as those which will appear in the sequel (§ 109. et seq.).

99. VI. Diagnosis of Syphilis.—This is often very difficult; for although the distemper has generally presented a modified and milder character in modern times, nevertheless cases sometimes occur which, owing to neglect, to constitution and habit of body, to treatment and manner of living, are as virulent as many of those which were described by writers in the sixteenth century, or of those which have been termed syphilitic cases. It will have been remarked, from what I have stated above, that I consider these latter as identical with the early manifestations of syphilis in Europe; the differences actually observed being only such as arise from the manner of infection—from the exudation from the cutaneous and other parts, during the constitutional disease, having infected these parts in persons with whom these exudations had come in contact, and from differences of race and other circumstances (§ 109. et seq.) That the disease assumes a different character as respects the different races, may be expected, in as far as the integuments are concerned; for, owing to the structure and visceral condition and functions of the skin, and to the asthenic diathesis of the dark-skinned races, and more particularly of the Negro, syphilis attacks these structures with greater severity than in the white race,—although even in this there are often exceptions,—and assumes in the former the character described under the head Yaws and other Syphilid Distempers. As regards the treatment, that found most beneficial in the one is also most beneficial in all the others. I have seen smallpox in the Negro in Africa, and yaws in the same race; and the difference of the former malady in the Negro from that observed in the white race is as great as that of the latter disease is from secondary syphilis in the white. The causes, efficient and concurring, are the same in character; the treatment is also the same; and this being admitted as respects yaws, the inference must necessarily extend to the other modifications of the distemper belonging to this category.

100. The diagnosis of Constitutional Syphilis, as it occurs in the present day in the white race, and after the virus has passed through many generations, is often very difficult, even when aided by the history of the case; and this difficulty is increased by the different tissues and parts which are secondarily affected, either singly or conjointly. Mr. Holmes Coute has classed the secondary effects of syphilis as follows, and to these I may add the tertiary:—

101. i. Secondary Symptoms or Effects.—

102. ii. Tertiary Effects.—1. Tubercles or guama.—a. Of the skin and cellular tissue; b. Of muscular and fleshy structures. 2. Inflammation of the periosteum. 3. Inflammation and enlargement of joints. 4. Diseases of the testes.—a. Inflammation and enlargement of one or both testicles; b. Atrophy or other structural lesion of the testes. 5. Inflammation of bone and its effects.—a. Ulcerations in the bones; b. Excavations of the bones; c. Caries. 6. Inflammation and structural change of the eyes, eyelids, or lacrymal apparatus. 7. Phagedenic ulceration of the scalp.—a. Without disease of the pericranium and subjacent bones; b. With disease of these parts. 8. Phagedenic ulceration of the pharynx.—a. Extending to the larynx, ear, and sinuses; b. Extending to the larynx, eustachian, &c. 9. General syphilitic cachexia.—a. Without any prominent visceral disease; b. With prominent disease of the viscera.
VENereal Diseases—Syphilis, Prognosis of.

103. It is not to be expected, that the lesions belonging to the first or the second of these classes of constitutional disease will appear singly. On the contrary, they are large and deep, associated in various forms or groups; affections of the skin being often complicated with those of the throat, tongue, gums, &c. Affections of the joints may be conjoined with inflammation of the periosteum and bones, and with phagedenic ulcerations. Even vascular tertiary lesions may be accompanied with one or more of those which are secondary; or, more correctly, certain secondary affections, such as those of the skin and throat, may persist, although one or more tertiary alterations are fully developed. Thus, in a case which I saw with Sir B. C. Bronze there were ulcerations of the throat, pharynx, larynx, nodes, pains in the bones, &c., consequent upon syphilitic eruptions and cutaneous ulcerations, which still remained, the pharyngeal ulcerations implicating the cervical vertebrae. The disease in this case was preceded by suppurating buboes. In another case, which I described with the late Mr. C. H. Turner, there were extensive ulcerations of the skin; nodes, caries of the bones of the nose and palate, inflammation of both eyes and eyelids, remarkable enlargement of the knee and elbow-joints, phagedenic ulceration of the scalp, and general cachexia. In other cases, in addition to affections of the bones and joints, there were phagedenic ulcerations of the pharynx, with inflammation and necrosis of the palate and nose, enlargement of the bodies of the testicles, and large ulcerating tubercles of the integuments.

104. The diagnosis of Syphilis depends chiefly upon the history of the case, especially as respects the existence of primary symptoms of buboes, and exposure to infection by direct or indirect contact, more especially by sexual intercourse, suckling, &c. (See the Causes, § 109. et seq.) The eruptions in the secondary stage will generally indicate the nature of the malady; but even as late as the third stage (§ 57-81.) on this subject may not be sufficiently considered, if other particulars be not sufficiently considered. The colour of syphilitic eruptions, although generally yellowish or coppery, especially before they ulcerate, may be of a brighter hue, if febrile action be present. In rare cases, the pustular eruptions may very closely resemble the eruption of small-pox; but a few days will disclose the differences. These eruptions and their rapid enlargement and ulceration in the early history of the disserter were very common, and hence the name of great-pox, very commonly given to them. Mr. H. Coote very correctly remarks that syphilitic eruptions do not always preserve the same type in the same individual. The scaly and tubercular, or the scaly, popular, and pustular, may be combined in the same case; and a scaly eruption may exist on the trunk and a pustular on the scalp. At the same time the dispassionate observer will admit that there is a difference as constitutional disease advances, Scaly and papular eruptions are often co-existent both terminating in desquamation, leaving copper-coloured stains. Large tubercles of the integument pass into deep, excavated, or phagedenic ulcers, and may be attended by the usual forms of rapia. Syphilitic scaly eruptions are generally circular, and more strictly resemble lepra, than psoriasis. The eruption on the trunk is often different from that on the extremities; on the former it is more generally erythematous, papular, scaly, and pustular; on the latter it is often tubercular, passing into deep ulcers with elevated edges, especially on the lower extremities. Rupia, however, may equally affect all parts.

105. Syphilitic erythema usually precedes other eruptions, but it may continue in the form of dull red or coppery patches, or co-exist with other eruptions. They are accompanied by a secretion resembling that of syphilitic lepra, the scales of which are dark, and differ widely from the silvery scales of lepra vulgaris. This eruption may extend over the whole body, causing the hair to fall off, and affecting the palms of the hands and soles of the feet. It spreads into mucous outlets and cavities, into the nasal, buccal, anal, vaginal, and others, where it causes ulcers, fissures, tubercular elevations, excoriations, discharges, &c. Lepra syphilitica often attacks and excoriates the scrotum, and is frequently attended or followed by foul ulcers between the toes, mucous tubercles about the arms, in the axilla, groins, or where the axillary or inguinal glands are allowed to accumulate. The elevation of the scales of lepra into copper-coloured tubercles is always, according to Mr. H. Coote, associated with impairment of the general health, and is an indication, during a mercurial course, that the medicine is acting injuriously, that the treatment should be changed, or at least that the patient should be allowed a more generous diet, and a moderate amount of stimuli. The cicatrices from syphilitic sores, it may be remarked, are often characteristic, being usually rounded, depressed, of a dull white hue, and irregular on the surface.

106. The tertian effects of syphilis may generally be recognised with greater certainty than the secondary. The history of the case, the antecedent symptoms and lesions, however remote, and the nature of these as inferred from their characters and succession, are to be taken into account. But there are hardly any of the lesions, which are termed tertiary, that are not of the remote effects of constitutional syphilis, when viewed and considered with reference merely to its own characters and relations. The mere enumeration (§ 101. et seq.) of these effects sufficiently indicates their nature; and are equally the results of neglected or injudiciously treated syphilis, as observed in the present day, and of the African yaws as observed by myself and others.

107. VII. The Prognosis of Syphilis is manifestly dependent upon so many circumstances as to be stated with much difficulty, and even with uncertainty. It depends not only upon the progress the dissembler has made, and upon the effects observed; but also upon the health and constitution of the patient previously to infection, and at the time of his coming under treatment. Nor should the mode of infection, and the course it has pursued, and its recurrences, or the constitution of the patient be constitutionally chronic, be overlooked. If the patient be young, in previous good health, be not exposed to fatigue, cold, or anxiety of mind, and not given to excesses of any kind, a favourable opinion may be given both in the primary and secondary stages of the distemper. But if his health, strength, and constitution be manifestly...
VENERAL DISEASES — SYPHILIS, CAUSES, ETC. OF. 1341

impaired; if he be dissipated, exposed to fatigue, and irregular in his habits; and more especially if the secondary effects be severe, be complicated, have been rapidly developed, or have reappeared after courses of mercury, or after other judiciously employed means, an unfavourable or at least a guarded diagnosis of syphilis has been, the danger of the case fully admitted, and due precautions for the guidance of the patient fully stated. In most cases ulcerations of the pharynx, owing to their disposition to extend to important adjoining parts, or to become phlegmonic, should be viewed unfavourably, more especially in the circumstances just mentioned. The severer kinds of secondary effects should also be much dreaded in infants; and they are always most difficult to remove in patients of all ages when they are produced by the new frequent modes of infection (§ 110. et seq.), which commonly prevailed in the 16th century, or by the discharges or exudations of secondary sores, either directly or indirectly coming in contact with the naked cutaneous or mucous surfaces.

108. The tertiary effects of syphilis are always attended by more or less present or prospective danger. But the imminence of the one, or the amount of the damage suffered upon the external aspect of lesion already produced, upon its complications and constitutional relations and effects, upon the history of the case, and upon the effects of appropriate treatment. When pharyngeal ulceration has become phlegmonic, or has extended to the larynx, to the bones of the face, and to the eyes, the patient is in great danger; and this is more extreme if the cervical vertebrae become implicated. The same prognosis may be given if, with general and increasing cachexia, pulmonary, paralytic, or dropical disease supervene, after obstinate, prolonged, or even rapid course of the distemper; whether in some of these cases life may be prolonged for a considerable time under favourable circumstances, and suitable regimen and treatment. In this far-advanced category of morbid results an opinion of the issue will be based upon experience of the effects of the most influenceful medicines, upon the local and constitutional association of the case, upon the previous and existing circumstances of the patient, upon the history of the malady, and upon various influences which have modified its course. In respect of the tertiary effects of syphilis, I may state, that an opinion respecting them should always be given with caution and reservation; even although circumstances may not warrant that opinion to be unfavourable.

109. VIII. THE EFFICIENT CAUSE OF SYPHILIS, AND THE CAUSES AIDING ITS OPERATION.—The former has been very generally recognised, and its effects admitted; and the circumstances of its application and operation have not been sufficiently shown and considered. The latter have been either overlooked or imperfectly estimated, especially as regards the successive changes, promoted and brought to maturity, as manifested in the secondary and tertiary results of the poison. The caution of syphilis has been disregarded, either from what has been observed in modern times, and from the common way of propagating the distemper at the present day. But the more general way by which this infection was produced soon after its introduction into Europe, and during its epidemical prevalence, has been alto-

gether overlooked; although, under the circumstances existing in these ages, it may be still propagated in the same ways, and its effects present as severe a character, and the same features as those which distinguished it in former times; and which still distinguish it in that form of the distemper which prevails in Africa, and which prevailed there from immemorial ages before it was introduced into Spain.

110. The contagion of syphilis at the present day, and for many years past, has arisen from sexual intercourse, either the male or the female being the subject of the primary disease. In these cases the infection is produced by the virus, poison, or morbid secretion of the primary sore. This mode is generally admitted, and is now, with very few exceptions, especially in Europe, the common mode, no other being acknowledged by many, the exceptions being altogether ignored. But I have had sufficient reason to conclude, that whenever a secondary venereal ulceration, seated on the integuments, or in the mouth and throat, produces a secretion or discharge, which comes in contact with a mucous surface, or with an abrasion of the cutaneous surface, or is even allowed to remain in contact with an unabraded surface, infection is liable to take place, and that this liability exists both in children and in adults. The communicability of secondary syphilis, especially when the sores have proceeded to secrete or produce a fluid exudation, was a well recognised fact in former times, and has been witnessed by myself during the course of my experience in several instances. It was a recognised fact by Dr. Colles; and although Hunter believed that secondary symptoms could no longer infect, Mr. Barrington remarks, when commenting on this belief, that "the facts (that they do infect) are so well established, that it is more easy to question the principle than to doubt the facts."

111. Judging from what I have seen in several countries and climates, and in children and adults in this country, I conclude, that the morbid secretion from secondary sores, if allowed to secrete, remain in contact with the more or less: faces or parts of a healthy person, will infect that person, provided that he be predisposed to, or susceptible of, the infection; and that the local contamination, at first confined to, and more particularly and severely affecting, the tissues first infected, will become general, and will the more readily and severely, by means of the secretion from the ulcers or sores produced in the course of the distemper, infect those to whom this secretion is either directly or indirectly applied. This mode of communicating the malady was often observed in all the varieties of it described above as syphiloid diseases, and under circumstances of the malady, from the end of the fifteenth until the close of the seventeenth century, or even later. The extensive prevalence of syphilis during these centuries, although imputed by many, and probably not without reason, first to a leprous diathesis, and afterwards to a scurvy diathesis, or to a complication of syphilitic with leprous or with scurvy symptoms, may be more correctly accounted for by the facts of the secondary, or early constitutional effect of the malady having become thus virulent contagious, both by this mode of communication, and by its successive propagation in this manner.
VENereal Diseases — Syphilis, Causes, etc. of

112. If we note the habits of the lower classes in those ages, the ready infection and the severity of syphilis are easily explained. As observed in the present day, with respect to yaws in Negroes, the contagion was produced by the secretion from the sores on the cutaneous surface, by intimate or immediate contact, much more frequently than by sexual intercourse. In the lower classes in Europe, in the 15th, 16th, and 17th centuries, the circumstances favouring this mode of communicating the malady were much more remarkable than in the Negro, from whose race the disease most probably originated; for amongst this race its antiquity appears to have been the greatest, and by this race the disease was communicated to the Moors and Jews in the North of Africa, and by them conveyed into the South of Spain, where it existed long before the expulsion of them from the Iberian Peninsula. The lower classes in Europe during the centuries of the earlier prevalence of syphilis were remarkable for their neglect of cleanliness, for their use of woollen night and day clothes next to the skin; for the habit of two, three, or more sleeping in the same bed, often in a state of nudity; for drinking and eating out of an earthen vessel; and for their and other social conditions favouring the communication of the disease, in its secondary stage, independently of sexual intercourse.

113. With the progress of civilisation, and with the knowledge acquired of the communication of the distemper by these means, the infection of it otherwise than by sexual intercourse became less frequent; and the virus more generally having to pass through the absorbent system, when the genitals were the seats of primary infection, was either arrested in the course of its constitutional contamination, or rendered more mild, and slower in producing its successive specific effects, than when infection was produced by the virulent secrections from secondary sores applied to parts which more readily admitted of constitutional contamination. The successive propagation of the distemper in this latter mode, and generally without the intermediate interruption and amelioration resulting from the action of the virus on absorbent glands, without the production of buboes — manifestly rendered the malady more rapid and more severe, and was the chief cause of the early prevalence of syphilis being in some respects different from what is observed of it at the present day, but in every respect similar to the varieties mentioned above (§ 84. et seq.); many of the influences producing these varieties actually having existed at the time of, and for ages after, the introduction of syphilis into Europe.

114. As observation rendered persons aware of *Dr. Winterton (An Account of the Native Africa, see vol. ii. p. 148.) remarks that "the yaws is not mentioned by authors as a disease which occur in Egypt, though, from the frequent communication of that country with those parts of Africa in which the disease is endemic, we might be led to expect that it would be imported. There is reason, however, to suppose that the disease was spread by the secretsion from the vesicular disease. He proceeds to remark that a Cop, who profess to cure the vesicular disease in its acute stage, prescribed "two coffee-cups of flux oil to be taken every morning fasting," directing no regimen further than to keep the patient warm. The pus, or other eruptions he covered with a red earth, common in some parts of Egypt. They gradually became dry and left no mark. At the end of three months a cure was effected. It is further stated, that those persons who have been affected and fully cured have no fear of a second infection.
venereal diseases — syphilis, causes, etc. of.

117. Several causes favour, 1st, the development of the constitutional disease from the local infection or primary sores; — and 2d, the aggravation and local manifestations of the syphilitic contamination, when it is not completely removed, but remains lurking in a more or less latent form, in the body. The most remarkable features of constitutional syphilis are the severe and even dangerous developments sometimes assumed by it after it has remained for several, or even for many, years latent in the frame. These cases present two difficulties — first, to estimate the influence of the poison in affecting the vital cohesion and conditions of the tissues in so permanent a manner as to render them liable to ulcerous changes and disorganisation after very remote periods; — and second, to recognise the effects of constitutional remedies upon these vital conditions and consecutive changes, and to determine how much of these effects may be imputed to the operation of the means employed, and to the efforts of nature, or of the vital resistance opposed to successive changes. It is impossible for these difficulties to be overcome without a satisfactory knowledge of the various circumstances which thus tend to develop the constitutional infection, and to aggravate this infection into dangerous local disease.

118. Observation satisfactorily and extensively conducted will demonstrate that all depressing influences acting upon the body after infection has been produced will favour the superelevation of the secondary upon the primary disease; and will even more remarkably develop the latent constitutional taint or contamination, wherever it exists, into active disease and disorganisation. Amongst these aiding and determining causes may be mentioned, among others, the consequences of infection; fatigue, debauchery, drunkenness, venereal excesses, unwholesome and insufficient food; want of sleep and sufficient repose; excessive exertion, exposure to extreme ranges of temperature; moist states of the atmosphere, and exposure to malaria in any form, more especially to insidious exhalations in hot countries. While these causes aid the constitutional infection in accelerating the changes resulting in local disorganisation, they also counteract the vital resistance opposed to these results, and throw down the barrier which the vital force raises for the protection of the organs of the body.

119. C. Infection of the fetus by one or both parents. — Congenital syphilis, or the direct transmission of syphilis to the unborn fetus, is a subject of considerable interest. That the syphilitic taint is more frequently in the father than in the mother appears from the fact that the disease is conveyed directly from the father by means of the seminal fluid to the ovum, for the father may first infect the mother, the disease being afterwards communicated by her to the fetus. Secondary syphilis, however, being a constitutional taint, like other constitutional taints, it may be transmitted to the offspring from either parent, in a more or less modified form. There can be no doubt also that secondary syphilis may be communicated to married women by their husbands without pregnancy having taken place; or even to them or to any one else by close contact, independently of sexual intercourse, when the circumstances stated above (§ 112.) favour the infection.

120. Dr. Porter mentions the case of a lady, who had become pregnant three months before the father’s first contraction of syphilis; and whose fetus died within a week from birth of unmistakable lepra. The circulation of the mother had therefore been poisoned at a considerable time subsequently to impregnation, although the father had never a sore capable of furnishing a drop of matter, and the mother never a symptom of any description, until an eruption appeared a few days before her delivery. Dr. Porter believes, “that the semen of a diseased man deposited in the vagina of a healthy woman, by being absorbed, may contaminate that woman without the necessary occurrence of a chancre or any open sore secreting matter in either the man or the woman.” Mr. Holmes Coote very correctly remarks (and his remarks bear out my own observations in a variety of cases) that “when the mother has once been infected with the syphilitic poison it becomes extremely difficult, if not impossible, to say when the taint will become extinct. The immediate effect, as regards the fetus, is to cause its death in utero. As the poison becomes less virulent, the child is born with the disease and perishes in a few days or weeks. Then comes a class of cases in which the characteristic eruptions break out some weeks or even months after birth; but the exact limits of these periods have not been, and perhaps cannot be, accurately ascertained. In illustration of these remarks, I refer to the following cases. In the first a respectable woman is infected by her husband. She is delivered consecutively of three dead children. At the expiration of thirteen years she gives birth to a living child which is covered by the usual eruptions shortly afterwards. In the second, a fine healthy and vigorous child is infected by her husband a few weeks after marriage. She is delivered of a dead child; after which she does not again become pregnant. But, eight years having passed, she suffers in her own person from the original taint.” (Op. Cit. p. 129.)

121. Whilst I was physician to the Infirmary for Children, cases illustrative of the above remarks, as well as of the following statements, were occasionally brought under my observation.—1st. That an infected mother may not communicate the disease to her infant. 2d. That an infected mother is very liable to transmit the distemper to the fetus or infant. 3d. That the mother has been infected several, or even for many years, has given birth to one or more dead children, and has had at last a living child, which soon after birth presented the syphilitic cachexia, with anaemia, copper-coloured lepra, and ulcerations of the nose, apoplectic fits, loss of teeth, and, perhaps, of the hair, mouth, anus, or genitalia. The patient was not sure that she had syphilis communicated to her by her husband; and the disease has disappeared, but she has been delivered of dead children; and after a number of years from the infection by her husband, the distemper has appeared in the throat and bones of the palate, or in other parts. 5th. The mother...
VENereal Diseases.—Syphilis, Causes, etc., op.

has been the subject of syphilitic eruptions, &c., has been apparently cured; but after many years has had a return of secondary symptoms, and been pregnant, either in the interval or at a later period. There is an opinion that this idiocy or derangement, and has continued in good health for several months or years, but has presented secondary symptoms subsequently. 6th. A woman has been the subject of secondary syphilis—of syphilitic eruptions, &c., and has communicated the distemper to the child given to her to nurse. 7th. Secondary syphilis in a child has been communicated to another child with which it has slept, the severer forms of secondary disease resulting. 8th. Secondary syphilis in a child has been by it communicated to its nurse, who has soon afterwards experienced the characteristic syphilitic eruptions, sore throat, alopecia, and other still more severe affections. 9th. A healthy woman has sucked, even for a few times, a syphilitic infant, and the secondary disease has been communicated to this woman, by this infant; she afterwards has sucked her own infant and given it the distemper.

122. These statements have been fully confirmed by my experience at the institution mentioned above, and in private as well as in gratuitous practice, during a number of years, and will readily be admitted by other experienced physicians. Indeed, they are fully confirmed by the writings of Dr. Colles, Mr. H. Coote, and by nearly all the old writers on syphilis. Dr. Colles remarks that the child may be infected after birth by a nurse suffering syphilitic ulceration of the nipple, or by its mother, under the same circumstances, if the disease of her nipple has been derived from a strange child; but that no instance is known of a child infecting its own mother, although it will immediately communicate the malady to a strange nurse. The infection of the nurse by a diseased infant manifests itself by syphilitic affections which cannot be distinguished from that succeeding primary disease—by ulcerations of the throat, &c., by cutaneous eruptions, and by the formation of most excretions about the pudenda, which are capable of infecting her husband, in whom they are likewise followed by constitutional effects. In him the ulceration of the throat has not the same venereal character; it is superficial, and its surface is covered with patches of whitish lymph. Dr. Colles believes that the disease may be further imparted to other members of the family by contact, the use of the same utensils, &c., for it is remarkable, he adds, that its contagious property increases as it extends further from its source. Its symptoms, he states, bear an exact resemblance to each other in different individuals; and in this third remove from the source of contagion, it is permanently fixed in the parts it first seized, and is of a much milder nature. If we compare the histories of the manifestations of syphilis in different ages, as furnished us by the most trustworthy writers down to the present day, and to still adduce the "Encyclopédie Méthodique," has classed it, the yaws, and venereal disease as the same maladies. Epilan. Note que les natures de Sainte-Dominique échappent à la vérole, qu'on croit avoir été éminente dans cette île. Quelques-uns ont cru que c'était un caractère de race grave et plus factieux encore que la vérole; mais il est actuellement prouvé, que c'est la même maladie que les Français ont appelée mal de Naples, et que l'Italien Français, chacun exprimant de deux fois l'ignorance d'un mal aussi honteux, et accusant ses voisins d'en avoir propagé la contagion." (Tomes viii. p. 2.)

* The yaws are inoculated at an early age in many places in Africa, in order to prevent subsequent infection; and syphilis is now practised in some places in Europe to prevent infection, as well as to produce a permanent cure of constitutional syphilis (see Syphilization in the sequel).

† SYDENHAM believed the yaws to be the same disease as syphilis. They are, and still more recently, the "Encyclopédie Méthodique," has classed it, the yaws, and venereal disease as the same maladies. Epilan. Note que les natures de Sainte-Dominique échappent à la vérole, qu'on croit avoir été éminente dans cette île. Quelques-uns ont cru que c'était un caractère de race grave et plus factieux encore que la vérole; mais il est actuellement prouvé, que c'est la même maladie que les Français ont appelée mal de Naples, et que l'Italien Français, chacun exprimant de deux fois l'ignorance d'un mal aussi honteux, et accusant ses voisins d'en avoir propagé la contagion." (Tomes viii. p. 2.)

123. D. Inferences.—As the result of observation and research, I conclude,—1st. That syphilis, in the various forms and modifications it has presented in different ages and localities, is derived from, and hence originally identical with, the indigenous yaws of the native Africans.—2d. That this identity or derivation is proved by the characters of both forms of disease, by modes of infection or contamination, by the susceptibility and unsusceptibility of both, as shown by inoculation, &c., and by the same treatment being appropriate to both.—3d. That the indigenous African or Ethiopic syphilis was communicated to the Moors and Jews in the north of Africa, and thence conveyed into Spain, and probably also into France and the north of Italy, even before the discovery of America.—4th. That the distemper was further diffused and rendered epidemic or pestilential by the expulsion of the Moors and Jews from Spain by Ferdinand, towards the end of the 16th century, and by the distresses consequent upon this act; the miseries and the horrible sufferings resulting from it, as well as the diseases diffused by it, being recorded by contemporary writers.—5th. That this occurrence shortly preceded the invasion of Italy by Charles VIII. of France, by augmenting the sufferings and distressing the inhabitants, increased the spread of the malady, and rendered it at the same time more virulent, acute, and fatal.—6th. That the diffusion, severity, and the infectious character of the malady were promoted by the distresses then prevalent in those countries, and for many years afterwards, by the prevalence of a leprous, or of a scrofulous diathesis in many, and by the habits and social conditions of communities, in those ages and countries.—7th. That there is sufficient evidence to conclude, that the disease existed as now stated, and had been propagated extensively, before the commencement of the yaws, or phoebe, or syphilis, which was said to have existed in America when discovered by Columbus, could have been conveyed by his followers into Europe.—8th. That the manifestations of the distemper, usually described as varieties of it, as yaws, epian, or as syphilitid diseases, or as pseudo-syphilis; the distinction which are noticed above (§ 84. et seq.), are merely modifications of the malady resulting from modes or sources of infection, race, social conditions and habits, food and regimen, neglect of cleanliness, treatment, &c., as already insisted upon (§ 111. et seq.).—9th. That whatever lowers the vital forces of the economy, and more especially a combination of causes producing this effect, will favour the infection of syphilis, the development of the constitutional contamination, and the outbreak of the distemper when it lurks in the body.—10th. That the parent
tainted by syphilis will often, but not always, communicate the disease in a more or less severe constitutional form, with marked local affections, to the fetus— with a severity often sufficient to destroy the life of the fetus, either previously to or soon after parturition; and that, in many cases where this was not the case, a febrile, scrophulous diathesis or more manifest tubercular disease will result. (See §§ 82, et seq.) — 11th.

That many of the circumstances and social habits which have been shown above to have favoured the dissemination and severity of syphilis for ages, after it was introduced into Europe, now no longer exist, excepting in limited localities; but when they have existed in more modern times, the distemper has presented a severity, and other characteristics displayed by it in former ages.— 12th.

That there is reason to believe that the disease existed in China from time immemorial, or at least ages before the period at which it became epidemic in Europe; but the extent, or the form, of its prevalence in that country at the present day I have not the means of knowing.— 13th. That inoculation, as practised for ages on children by the negroes on the Gold Coast, for the prevention of smallpox, is of value in the prevention of some of the lesions of the Continent against syphilis (see Syphilisation, §§ 155, et seq.), may be expected to lead to some important results.

123. IX. TREATMENT.—I. HISTORY OF.—It would appear, from the earliest writings respecting the discovery of America, that the disease existing in Hispaniola, when discovered by the Spaniards, was a variety of syphilis, if not the same distemper, or the same as the yaws existing at the same time, and for centuries previously, in Africa (see §§ 84, et seq.); that this disease was treated successfully by the natives of Hispaniola by the decoction of guaiacum; and consequently that guaiacum was employed by the Spaniards who had there contracted the disease. We accordingly find many of the early writers on syphilis, especially from the commencement of the middle of the sixteenth century, as De Hutten, Deldaro, Ferro, Pelle, Zene, Gali, Monasterio, Haring, also about, Guanacos, &c., recommend guaiacum for its cure. Although a very few writers mention, towards the close of this century, mercury as a remedy for syphilis, yet it was not until the middle of the seventeenth century (1649) that Bonnemont asserted that this malady could be cured by mercury alone. Some years afterwards Menendez (1689) and von Hammon (1674) proposed the question, whether or no mercury should be preferred to guaiacum in the treatment of syphilis? Since then, and especially from the commencement of the eighteenth century until the beginning of the nineteenth, mercury has been the almost universal remedy for this distemper; and corrosive sublimate was the most employed preparation of it; more than one hundred writers (117), during the eighteenth century, alone recommending it. Ciessa and Blanchard prescribed sarsoarpil; the former stating that this medicine was adopted congenitally, sarsoarpil, for the cure of syphilis, as it prevailed among them; and numerous Spanish and Portuguese writers in the sixteenth and seventeenth centuries employed it, in conjunction with guaiacum and saussfras; this combination being very generally resorted to as a part of the treatment of syphilitic cachexia down to the present day.

124. Early in the eighteenth century, Wilkoshovy (Salivation shown to be of no use or efficacy in the cure of the Venereal Disease, 4to. Lond. 1723) contended against the practice of salivation, then so generally adopted; and in 1779, Cockburn affirmed that all venereal ulcer will heal under a local treatment merely; and that mercury should be resorted to only when constitutional symptoms appear. Early in the present century several army surgeons, probably instructed by their observations in Spain and Portugal, where the practice of salivation had almost disappeared, claimed the treatment of syphilis without mercury; and from 1820 to 1830, experiments were made in the Hospitals of Sweden—a country where scientific progress is always in advance—and in Hamburgo, on the non-mercurial treatment of this distemper. In the present day there can be no doubt of the success of this treatment in the majority of cases; and that the worst states of the disease—the most prolonged and most dangerous forms—have been those, for which mercury had been most abundantly employed at an early stage, and the most copious salivation produced and continued for the longest periods.

125. In the summer of 1825 the iodide of potassium was first prescribed by me for the cure of secondary and tertiary syphilis, and the prescriptions were then prepared by Mr. Monois, the well-known operative chemist. For this purpose I had been long time prepared for me an iodide of sulphur, in order to employ it in similar cases; but I soon relinquished the internal use of the latter for the former, as being, even in small doses, too irritating to the digestive mucous surface. In the following year, I had recourse, in the case of E. L., Esq., M.P., to the use of iodine. This case, the nature and history of which was well known to Mr. C. Brevon, of Upper Harley Street, had been treated unsuccessfully by mercury in every conceivable form and combination; and when it came under my care I viewed the severe symptoms, which were seated chiefly in the large joints, as the result of the combined effects of syphilis and mercury. Iodine was had recourse to successfully in this case. The correspondence between this gentleman and myself respecting the treatment during his absence from London is still preserved by me in proof of the early and successful employment of iodine and its preparations for secondary and tertiary syphilis.

126. Since 1825 I have prescribed these preparations, whenever I have been consulted in cases of this nature; but in some, and in certain stages and states of the disease, they have failed, as in two instances which lately came before me.
1846

VESTERAL DISEASES — SYPHILIS, TREATMENT OF PRIMARY.

and which I remitted to the care of Mr. H. Lee, for the employment of his plan of mercurial fumigation. Most of the severe and dangerous cases of syphilis which I have had an opportunity of witnessing have been reduced to this state by an excessive or an improper use of mercury; and it has been seen especially in those cases that the use of iodine, especially the iodide of potassium has been most successful. The worst symptoms which have been too frequently ascribed to local manifestations of syphilis, especially affections of the periorbital region, bones, &c., have been demonstrated to me to have been the results of excessive doses of calomel alone, very commonly given in hot countries, during the early part of the present century, for the cure of fever. At one period of this it was attempted to bring the system under the influence of mercury in these maladies, but the practice very generally failed; and in some of these cases, in which recovery took place, disease of the periosteaum was the result.*

127. ii. Treatment of Primary Syphilis

— A. The intensity of cure in this stage of syphilis are, — 1st. To destroy the poisonous ulcer and heal the purulent discharges as rapidly as possible, — and 2d. To prevent the contamination of the constitution. The first intensity is best accomplished by touching the sore with nitric acid, nitrate of silver, or any other escharotic. The penis may afterwards be wrapped in a rag dipped in warm water. An aperient may also be given, and rest and low diet enjoined. If the sore has lasted above a week, it may still be expedient to destroy it; but there will not be the security against constitutional contamination, which an earlier recourse to these means might afford. When, however, the chancre consists of a well-marked indurated lump, or when the penis is swollen and inflamed, the patient fevers, or when there is swelling or tenderness in the groin, then the above local treatment is no longer applicable; and mild local applications, consisting of the black wash, lotions containing tannin or catechu, or of other substances, in a similar state, may be employed. If the contaminating secretions, may be prescribed to the affected parts. If there be much irritation, the penis should be enveloped in a poultice, or in a compression of boiled cannelle flowers and poppy heads, and the patient kept in bed. If induration exist, an ointment with calomel may be applied.** Afterwards, during the indolent and granulating stages, the sores may be treated with any astringent lotion, and be touched occasionally with nitrate of silver, or sulphate of copper. (Dr. M. C.)

128. B. The prevention of the constitutional contamination of syphilis was formerly carried on by a recourse to mercury contemporaneously with the treatment of the primary sores, the belief being general that where this object was not attained by means of this substance, the disease would infallibly proceed from bad to worse. Had, however, the malady been studied with a due reference to its origin and to its treatment, during the earlier periods of its history, as well as to the treatment of the constituant maldy, of which I have contended that it is merely an extension and modification, a different method of cure would have been instituted; and a recourse to mercury would have been either reserved, or entered upon in such a manner, and with such precautions, as would have secured successful results. The modern opinion, however, is, that every case of primary syphilis may be treated without mercury; that the too profuse administration of it may be injurious; and that there are many cases which do not admit of its use at all; but that in the right cases the moderate and judicious use of mercury removes the existing symptoms, and renders the patient far less liable to a relapse.

129. Mercury is either not required or not admissible under the following circumstances, — "When the primary sore has been destroyed, or has healed within seven days from its commencement; when it is much inflamed, irritable, sloughing, or phagednie; when the patient is feverish and irritable; when a bubo is present; when the health or constitution has suffered from attacks of syphilis or the use of mercury; when mercury is known to cause rapid salivation, or to occasion lose of flesh, sore throat, night sweats, or mercury erethism; and when serofulose disease is manifestly pronounced, or when tubercular constitution is manifestly pronounced. Then there be more of these contra-indications, and more especially if the sore be indurated, mercury may be given; not because absolutely necessary to a cure, but because it has been proved by experience to hasten the cure of the primary, and to lessen the chance of secondary symptoms." (Dr. M. C.)

130. But, as Mr. H. Coote has justly stated, "every form of primary syphilitic disease may be followed by constitutional affections, the nature and the duration of which no one can predict," whether the treatment be mercurial or non-mercurial. The want of fixed opinions as to the treatment of the disease displays itself in all the countries of Europe; and although it causes much uncertainty and distrust of the use of remedies, the injurious recourse to the excessive use of mercury, so common in former times, is no longer adopted. The most important question, however, is the frequency of constitutional disease after primary syphilis, when treated with, or without mercury, for the primary affection is, in far the greatest number of cases, an evil of comparatively little magnitude. Secondary syphilis, when once established, is a disease of which no one can foretell the termination. Its various phases, its succession and complication, are almost beyond the reach of our knowledge, and often out of the

* The following interesting case illustrates this fact: it occurred more recently than the period above referred to. Some years ago, a gentleman trading to the west coast of Africa was attacked by fever, and was treated by calomel given in scrupule doses every three or four hours. He recovered from the fever, and returned to England. I was called to see him soon afterwards, and found him completely hemiplegic, with two large swellings of the periorbital region. Having heard the account of his case, that he had never any venereal symptom, primary of secondary, that he had taken an excessive quantity of calomel during the attack of fever, I inferred that a tumour of the dura mater, as well as of the periorbital region, had resulted from the calomel, and now pressed upon the brain. The iodide of potassium was therefore prescribed, and the rapidly recovered the use of both sides, the paralysis disappearing with the subsidence of the periorbital tumours. He has continued in good health up to this time.

** While this was passing through the press I was called to a lady similarly affected to the above case, after the preceding use of mercury for hepatic disease. The iodide of potassium has already been very beneficial to her, but sufficient time is not yet elapsed to show the full results.
sphère of treatment. Dr. Heaven treated 105 cases of primary sores without mercury; secondary symptoms followed in eleven instances, and all these were cured without mercury, excepting one obstatine case. In the report of the Army Medical Department from December 1818 to December 1819, 1863 cases of primary chancre were cured without mercury out of 1940 cases, nineteen year preceding; the average time required for their cure being twenty-one days, when bubo did not exist; and forty-five days when bubo was present. The average time for the cure of secondary symptoms without mercury was from twenty-eight to forty-five days. In the above period, 2927 cases of primary affection were treated with mercury; secondary symptoms occurred in fifty-one of them. The average time for the cure of primary symptoms without bubo was thirty-three days; with bubo, fifty days; and for the cure of secondary symptoms, forty-five days. Of two cases treated by Mr. Green without mercury, one occurred in sixteen cases, six only suppurated; and constitutional disease, preceded by febrile symptoms, followed in nine cases.

131. From these data, it will be seen that the balance of advantages is not much in favour of mercury; and yet there are a few cases which cannot be cured, or at least not so soon or certainly cured, without this mineral, when used in a judicious manner. The opinions of some of the ablest recent writers as to the use of mercury for primary syphilis appears to accord with those of H. Lee, Dormett, and Acton; and upon the whole with the results of my own experience, which agrees also with the following remarks by Mr. Holmes Coote: "I am far," he states, "in undervaluing mercury as a remedy in syphilis; on the contrary, it is the most certain and powerful remedy we possess; but it requires to be administered with caution. The best method of securing a patient against the invasion of secondary symptoms is by destroying the primary sore, when small and manageable, by caustic; next, by healing the primary sore when that measure is impracticable, as quickly as possible, without detriment to the patient's health. If we salute a patient in whom a superficial sore is running its usual brief course of two or three weeks, we positively do the man an injury. But if induration should occur, either in the base of the sore as in the inured chancre, or in the cicatrix, a course of mercury, judiciously administered, is invaluable." The rules which should guide the treatment of chancres, are,—1st, to destroy, as rapidly as possible, the syphilitic virus, by applying the nitrate of silver, the strong nitric acid, or the acid nitrate of mercury, or the Viennese paste, to the sore when it is small, and spread in a little butter, or other medium; 2d. For sore cases which are not indurated, spread freely, and show signs of incipient granulation, the administration of mercury is injurious, as retarding the healing process, and not protecting the patient from secondary symptoms;—3d. When induration exists in the slightest degree in or around the primary sore, mercury should be continued; 4th. When after seven days, it shows no disposition to heal, then mercury is required;—4th. Mercury is either inadmissible, or not required, or even dangerous, for phagedenic and slothing chancres, and in the other circumstances above noticed (§§ 129, 156). The longer a syphilitic sore continues unhealed and secreting the contaminating matter, the greater the risk of constitutional infection.—6th. The more robust the constitution, and the more perfect the general health, the risk of secondary symptoms from primary sores appears diminished; but this vital resistance to contumacy should not prevent the early cure of chancre, more especially when it is indurated, nor prevent a recourse to mercury if the sore has been neglected or of long continuance.

132. Having determined, after due consideration, to have recourse to mercury, the selection of the preparation and mode of exhibiting it require some attention. The preparations which are most suited to the primary disease, when there is no bubo, are the hydrargyrum cum creta and calomel, and in some cases the pilula hydrarg. chloridi composita. The other preparations of mercury, especially the most resolvents and the belch chloride are more beneficial in other states of the distemper. The dose, and frequency of exhibiting the hydrargyrum cum creta or calomel, require no remarks. They should be regulated according to the state of the patient, and their effects upon the bowels. Calomel generally requires to be conjoined with small doses of opium, or with the pilula saponis composita, but in this latter combination the dose of calomel should be much increased. The object is to produce a slight soreness and sponginess of the gums, with a very slight salivation when indurated chancres exist, and to continue it for four or five weeks, preferring in the latter case the longer period. The dose of the medicine should be regulated according to its effects. During this course, the regimen of the patient should in part depend upon his state of health when commencing it. He should live regularly but not too low. If he be in ill health in other respects, the treatment, and regimen, and diet suited to his state should be prescribed. In general, excesses in food and wine should be avoided, and whatever is calculated to disorder his digestive and biliary organs. The clothing of the patient should be warm; if he is undressed, 

133. C. Gangrenous chancres, when it occurs in strong, sanguine, phlegoric, or healthy persons, is usually the result of excessive inflammatory action, and requires large vascular depletions, free purging, and afterwards—3d. For sore cases which are not indurated, spread freely, and show signs of incipient granulation, the administration of mercury is injurious, as retarding the healing process, and not protecting the patient from secondary symptoms;—3d. When induration exists in the slightest degree in or around the primary sore, mercury should be continued; 4th. When after seven days, it shows no disposition to heal, then mercury is required;—4th. Mercury is either inadmissible, or not required, or even dangerous, for phagedenic and
causes. In such cases, the application of opiate mixtures and camphorated lotions to the sores, of strong nitric acid, if it spread; and opium and camphor, or ammonia, the fixed alkalies and tonics taken internally, aided by a generous diet, beef-tea, wine, &c., are indispensable.

134. D. Phytophal is sometimes caused either by balanitis, or by one or more ulcers under the prepuce. In these cases there is more or less discharge. A chancre is often detected by local hardness and tenderness. If the prepuce be elongated, and cannot be retracted, circumcision may be advisable; but generally it will be sufficient to split the prepuce so as to enable the parts underneath to receive due attention, and the treatment which the character and progress of ulceration may require. The frumen is not unfrequently perforated by a chancre; and it then requires to be divided. In the circumstances now stated, the duration of the chancres, and the conformation of the parts, may lead to the supposition that the use of antiseptics increases the risk of constitutional contamination, and requires, unless in very recent cases, a recourse to mercury. A chancre in the urethra requires astringent injections, preferably such as contain the bi-chloride of mercury, and a course of this medicine if not contra-indicated by the state of the patient.

135. iii. The non-mercurial Treatment of primary syphilis may be adopted in the circumstances above stated (§§ 131, 132.), or even in others where it may be considered prudent or advisable to have recourse to means which will improve the general health, and enable the constitution to resist the invasion of the poisons virus. If there be debility or impurity of the digestive and assimilative functions, tonics, the chaulybeates; the preparations of cinchona, of sarsaparilla, or of guaiacum; end-liver oil, simple or medicated; the compound decoction of sarsaparilla, with or without iodide of potassium and liquor potassium, will be found the most deserving of confidence, especially if prescribed appropriately to the circumstances of the case, and if the patient live regularly, and avoid intemperance of all kinds, and all causes of exhaustion (§ 118.).

136. iv. Treatment of Bubo.—Mr. H. Cooke states that he knows of no relation between the occurrence of bubo and the frequency of secondary syphilis; and he believes the idea that a copious suppuration from the groin eliminates the venereal poison to be unfounded. "When swelling of the glands occurs in conjunction with primary syphilis, or is supposed to depend upon the syphilitic poison, venereal frictions are directed upon the thighs, that the mineral may pass through the enlarged parts." In more chronic enlargements, the swelling may be covered by a pustule of the uracum hymenoeum, or of the ungualium annunseatum, cum hydrgyno. "Leeches are not often required to an inflamed bubo, but they may sometimes be applied with advantage." The existence of suppuration should not suggest an early recourse to the lancet, as absorption often takes place after the skin has become red or even thin. Absorption of the matter from suppurating buboes does not add, in Mr. H. Cooke's opinion, to the patient's danger of secondary syphilis. An opening, when required in a suppurating bubo, should always be made in the long axis of the thigh. If any bowing of matter occur, particularly in serofulose persons, who are most liable to buboes, tonics, with a restorative and digestible nourishing diet, are required.

137. The treatment advised by Mr. Drury and Mr. H. Lee, for bubo is very different from that now stated. The former writer remarks that the first indication is to produce resolution of matter within the bubo—by rest, aperient and saline remedies, by diet, leeches and fomentations. The application to the chancres must be soothing, and mercury, if being administered, should be at once given up. As soon as the tenderness is relieved, pressure by means of a compress and bandage, or by placing a weight on the part as the patient lies in bed, is useful. Even if matter does form and does not seem inclined to come to the surface, the iodine paint, cold lotions, aperients, tonics, and pressure will sometimes cause it to be absorbed. But if it increases, and the skin becomes inflamed and shining, a puncture should be made, and the case be treated as a suppuration, and described as a case of the most distressing nature. In this quotation is the abandonment of mercury if it has been already prescribed. My observation in former days has induced me to agree with Mr. H. Coote in the recurrence to mercurial inunctions on the thighs, as they produce a complete effect upon the constitution, and may be used with advantage in cases of chronic bubo, combined or not with primary disease." Suppurating buboes, or solid inguinal swellings, will often disappear under this treatment, which, to be effectual, he advises to be done in the following way:—"The patient sitting before the fire, should rub on the skin at the inner part of the thighs a drachm of the strong mercurial ointment every night, or every night and morning. He should slip on a pair of drawers and go into bed, that the absorption of all that which sinews the skin may go on. The patient should not be allowed to wash the part except at intervals, to prevent the skin from being chafed." The introduction of a drachm or two of mercurial ointment into the axillas when in bed will generally produce the mercurial action when it is required in other circumstances.

138. In cases of indolent bubo, the indication is to improve the general health, by sarsaparilla, tonics, and the other means advised above (§ 135.). For these, change of air, sea voyaging, removal to a warm and dry locality, and digestible food are the most beneficial means of care. The heat of iodine is sometimes of service both to these, and in the chronic enlargements of the inguinal glands, but it is not so beneficial as the internal use of the preparations of this substance, which, when used internally, should be combined with either the liquor potassium, or with either of the carbonates of potash, and be prescribed with the most suitable medicines. If sinuses form, or if cough or phlegm occur, or if the ulcers become irritable or much inflamed, the means suitable to the case, both internal and external, should be employed.

139. v. Treatment of Constitutional Syphilis.—d. Of secondary affections. It has been contended by some recent writers and stated above (§ 46.), that the simple and phagedenic sores are rarely followed by constitutional syphilis, whereas the indurated chancres rarely if ever fail to be succeeded by the secondary disease. Mr. H. Coote disputes these positions, and concludes
that secondary symptoms in large proportion ensue after every variety of simple and non-indurated chancre. After primary phagedaena, too, secondary symptoms may be dreaded, and no lapse of time seems to render the patient's constitution free, the secondary disease paralyzing all of the powers of the body except without a satisfactory result, or when they appear to have been injurious. It is in these latter circumstances, and especially where a protracted course, or a too liberal exhibition of this mineral, has been directed, without avail, that the preparations of iodine, especially the iodide of potassium, in due solution and combination, according to my observation, have been most beneficial.

143. The preparations of sarsaparilla, especially the compound decoction, are always productive of great benefit. They may be prescribed either subsequently to a course of mercury or of iodide; or the bichloride of mercury, or the iodide of potassium may be taken with the compound decoction of sarsaparilla, or with the fluid extract or syrup. In some states of secondary syphilis, the muriate or the nitrate of ammonia may be taken in tonic and aromatic infusions, in as large doses as will not offend the stomach, or until the acids may be tried, either in weak dilutions or in the infusions just mentioned. But in most cases of secondary syphilis, characterised by much debility and loss of flesh, or by anaemia, few means are so generally useful as a prolonged course of the bichloride of mercury in the tincture, or compound tincture of cinchona, in the proportion of half a grain or a grain to the ounce of the tincture, a drachm, or a drachm and a half being taken twice or thrice daily in a little water, according to the circumstances of the case. When the throat, palate, or other parts of the mucous surfaces are much affected, this combination, or the bichloride in the syrup or fluid extract of sarsaparilla, aided by gargles containing the bichloride, or by mercurial fumigation, is very frequently efficacious.

144. In cases of indurated chancre of considerable duration, in most cases of secondary syphilis, and generally in those in which the blood demonstrates a great diminution of red corpuscles, an increased amount of albumen, the fibrin not being materially altered in quantity. These results should not be overlooked, as they indicate the propriety of caution in the exhibition of mercury, and of selecting the mode of exhibiting it now advised; or of adopting the preparations of iodine, and especially the iodide of iron, prescribing it in the syrup of sarsaparilla.

145. During the treatment of constitutional syphilis it should always be kept in recollection, that whatever depresses the vital force, or impairs the general health, tends in favour of the bichloride *, and my own experience of its effects, have rendered me partial to the adoption of it, in preference to other preparations, when a recourse to mercury should be had.

142. The iodide of potassium is often of great service, especially when a recourse to mercury is considered inexpedient or improper (§ 129.), or after the course of mercurial remedies has been tried without a satisfactory result, or when they appear to have been injurious. It is in these latter circumstances, and especially where a protracted course, or a too liberal exhibition of this mineral, has been directed, without avail, that the preparations of iodine, especially the iodide of potassium, in due solution and combination, according to my observation, have been most beneficial.

143. The preparations of sarsaparilla, especially the compound decoction, are always productive of great benefit. They may be prescribed either subsequently to a course of mercury or of iodide; or the bichloride of mercury, or the iodide of potassium may be taken with the compound decoction of sarsaparilla, or with the fluid extract or syrup. In some states of secondary syphilis, the muriate or the nitrate of ammonia may be taken in tonic and aromatic infusions, in as large doses as will not offend the stomach, or until the acids may be tried, either in weak dilutions or in the infusions just mentioned. But in most cases of secondary syphilis, characterised by much debility and loss of flesh, or by anaemia, few means are so generally useful as a prolonged course of the bichloride of mercury in the tincture, or compound tincture of cinchona, in the proportion of half a grain or a grain to the ounce of the tincture, a drachm, or a drachm and a half being taken twice or thrice daily in a little water, according to the circumstances of the case. When the throat, palate, or other parts of the mucous surfaces are much affected, this combination, or the bichloride in the syrup or fluid extract of sarsaparilla, aided by gargles containing the bichloride, or by mercurial fumigation, is very frequently efficacious.

144. In cases of indurated chancre of considerable duration, in most cases of secondary syphilis, and generally in those in which the blood demonstrates a great diminution of red corpuscles, an increased amount of albumen, the fibrin not being materially altered in quantity. These results should not be overlooked, as they indicate the propriety of caution in the exhibition of mercury, and of selecting the mode of exhibiting it now advised; or of adopting the preparations of iodine, and especially the iodide of iron, prescribing it in the syrup of sarsaparilla.

145. During the treatment of constitutional syphilis it should always be kept in recollection, that whatever depresses the vital force, or impairs the general health, tends in favour of the bichloride *, and my own experience of its effects, have rendered me partial to the adoption of it, in preference to other preparations, when a recourse to mercury should be had.

* Dr. Dronod, Professor at Halle, prescribes the bichloride as follows: — 1/2, hyparsip, bichlorid gr. xii, solvina aqua distillata q. s. et adde mice pannis, et saccari adii, 4, q. s. ut habitur librae cc, sing. ar. 1. The pills are to be rolled in powdered Canella bark; and on the first day four pills are to be taken (1/4 of a grain) on the second day none; on the third day six pills; on the fourth none; on the fifth to eighth pills; on the sixth none; on the seventh day ten pills, and so on, until the twenty-seventh day. Then take thirty pills a day. The treatment is then complete; but in some instances of severe secondary symptoms they are to be carried even further. The pills may be taken with water. 1/2 of the dose is to be shunned. I have been consulted by patients for whom this treatment has been adopted; but the cases have been too few to allow the conclusion respecting it. It is merely a modification of the well-known treatment advised by Van Swieten.
healthy, temperate, or warm and dry atmosphere, as to promote the constitutional powers; improvement in the healthy appearance of the patient generally indicating the success of the medicine employed.

146. The local treatment of secondary syphilis consists wholly or between, or sulphur balsam for the eruptions; of the application of lotions of corrosive sublimate, or eau-fortis containing the unguentum hydrarg. nitrati, or the unguentum hydrarg. nitrati, especially when the eruptions are severe, or are leprosous or tubercular. If itching, or irritation be experienced, lotions or frequent sp칭 the parts with a saturated solution of the bibonate of soda in any emollient fluid will generally be of much service. Dr. Druitt states that it" for the common excoriated sore throat, any soothing detergent gargle will do. When there are ulcers, it is advisable to use gargles of corrosive sublimate; and when the ulcers are indolent they may be touched with the linimentum mercuris. Mercurial fumigation is also occasionally of benefit. It is effected by putting a scapule of red sulphur, or of the common black oxide, or twice the quantity of mercury with chalk, on a heated iron, in moderation, and inhaling the vapour,—a heated penny piece in a tea-cup will answer the purpose.* When a foul ulcer is

* Mr. Henry Lee has given (Transact. of Med Chirurg. Society of London, vol. xxx.. p. 335) the following directions as to the use of mercurial fumigations:—

"Finding from experience that it was the light-coated side alone which volatileized, and produced its effects upon the patient's constitution, and having reason to believe that the light colour depended upon the presence of albumen, I performed a series of experiments with calomel alone, or mixed in a certain proportion with the grey oxide. The general result of these experiments has been, to satisfy me that, for the purposes of mercurial fumigation, five or ten grains of calomel alone is, in ordinary cases, quite sufficient; and that when the grey oxide is used, the admixture of a few grains of calomel will facilitate its sublimation and insure its medicinal action."—

"Upon making comparative trials with calomel alone and combined with steam, it was found to act more certainly and with greater regularity in the latter case.

"The plan which I have adopted is very simple. Two small balls of spirt procured in which the methylated spirits (much cheaper than spirits of wine) is used; over the lamp is a thin metallic plate, upon which the ten grains of calomel are placed; over the second lamp is a small cup of hot water. A small cone-bottomed chair is placed over the lamps, and the patient sits upon it. He is then enveloped, chair and all, in a blanket; at the expiration of a quarter of an hour or twenty minutes he rolls himself up in the blankets and goes to bed. For patients to whom it may not be convenient to procure the spirit lamps, the mode of proceeding may be varied as follows: The patient is directed to heat a thick tile in the fire; this is then put into a night stool, and a gallon full of warm water placed upon one corner of it. The calomel powder is then sprinkled over the rest of the tile, and the patient sits over it, being enveloped, as before, in a blanket. This mode of applying the vapour is very convenient in cases of affections, either primary or secondary, of the generative organs. It is not necessary for either case that the patient should breathe the mercurial fumes. It is remarkable how soon the patient is affected by the influence of the mercury by this simple means; and, according to my experience, how effectually it acts in cases both of primary and secondary syphilis. Its great advantage, however, consists in the very little constitutional disturbance produced by it, and in the persistence of these symptoms of irritation and debility, both mental and physical, which the prolonged internal use of mercury is so apt to occasion. This treatment, as in the use of the mercurial fumes, so, I am happy to say, has excited no such complaints as those of the skin, which have been frequent in other cases. It is, however, necessary to be careful that the skin is not exposed to the slightest degree of cold, for the safety of the patient.

* Mr. Coyte describes this bath as follows:—The clothes having been removed, and a suitable bathing dress supplied, the basher is conducted into a hot apartment, where he is allowed to sit and excommuniate himself to the increase of temperature. During this time the body becomes covered with a tolerably profuse perspiration. Next he is conducted to another apartment, where there is a high degree of heat (118° F) and cold water is applied. The patient is advised to keep himself as close as possible to the water, and to drink water and hot wine as his taste dictates, or take this process performed by an attendant.
either of the carbonates. In cases where mercurials have been freely employed, and especially where there is reason to infer that the affections of the periosteum or bones has been caused or aggravated by these medicines, or where there is doubt whether or no any of the tertiary affections have been caused as much by mercury as by the distemper, the decided use of the iodides of the fixed alkalies is generally the most beneficial. In cases manifesting more or less anaemia (See §§ 143, 144.), the courses of iodides, and still more those of mercury, should be followed by a course of the iodide of iron taken in syrup of sarsaparilla.

149. If the periosteum or bones be diseased, still greater caution in having recourse to mercury is required, although in strong constitutions, and where mercury has not been previously given, full doses of calomel and opium, or of these with camphor, will often induce the treatment with benefit, and they may be continued or modified as long as they continue of service, and afterwards the iodide may be prescribed, increasing the doses until success result from it. I have generally prescribed this medicine in the following combinations.

150. It generally will be of service to take the iodide in weak solutions, even when it is prescribed in the largest doses. If it relax the bowels, a few drops of tinctura opii, or a little tinctura camph. comp. may be added to each dose; or, the iodide and the alkalies may be taken in the compound decoction of sarsaparilla, to which a tonic or aromatic tincture, or an opiate, may be added, according to circumstances. When this remedy succeeds in removing the venereal affection, it should be continued for some weeks afterwards, gradually diminishing the dose. In some cases it causes irritation of the mucous surface of the throat, nostrils, and eyes, with a copious defluxion, or pains at the region of the stomach, or irreglar febrile symptoms. As it is more hazardous when the iodide has been given in too large doses, or uncombined with the carbonate or solution of potash. When taken thus uncombined, the acid in the stomach decomposes the iodide and the free iodine irritates the mucous surfaces.

151. In cases of ulceration of the pharynx, or larynx, or of disease of the bones, of the palate or nose, mercurial fumigations may be first tried, if mercury has not been already employed; but cure should be had not to allow it to affect the mouth. Sarsaparilla, with a cautious use of the iodide of potassium and sedatives; the application of a strong solution of the nitrate of silver, or of the bichloride of mercury to the ulcerated surface, and of terebinthin-eucampos to the throat externally, are often beneficial. Gargles containing either the bichloride or the iodine, neither of these substances being in such quantity as to occasion much irritation of the throat, may also be tried. In all these the utmost attention and care are required. When tuberculated or other eruptions assume the characters of open sores or ulcers, the simple or compound tincture of iodine will be most advantageously applied to them, in modes and in degrees of dilution varying with their appearances.

152. When nodes are formed, the pain and consequences which often result, require iodides, sarsaparilla, and opiates, with light nutritious diet, residence in a warm and dry air, and blisters over the affected parts. The blisters often should be repeated, in order to prevent, by the external discharge occasioning new irritation, to, or disorganising the osseous structure. If mercury have not been employed, the blistered surface may be dressed with strong ointment, and either with opium, or morphia; and the diet and regimen duly regulated, with strict reference to the several peculiarities of the case, to the extent to which the general contamination and cachexia may have advanced, and to the state of the local affections.

153. VII. Syphilis in Infants and Children. — The treatment should be directed not merely to the infant or child, when the state of either admits of any hope from treatment, but more especially to the parents. For these as well as for the child, a mercurial course, if not previously had recourse to, should be prescribed: and in the majority of cases, the bichloride of mercury, exhibited as above (§ 141.) or combined with either of the tinctures of cinchona, will be found to be most effectual. Subsequently the iodide of potassium or iodide of iron and the preparations of sarsaparilla may be employed, according to the peculiarities of the case, more especially if anaemia be very manifest. It has been recommended for children to rub ten grains of mercurial ointment daily into the axilla or soles of the feet, or to administer half a grain or a grain of hydrargryum cum creta every night until the symptoms disappear. But the disease is not so completely eradicated by these means as by a judicious exhibition and management of the bichloride, especially when followed by the means just named, varying the dose, and the vehicle in which it is prescribed, with the age and circumstances of the case.

154. X. Syphilisation, or the inoculation of syphilis, has recently attracted attention not only as a cure, but as a prevention of any future occurrence, of the disease; observed especially when the iodide has been given in too large doses, which are sometimes beneficial. Gargles containing either the bichloride or the iodine, neither of these substances being in such quantity as to occasion much irritation of the throat, may also be tried. In all these the utmost attention and care are required. When tuberculated or other eruptions assume the characters of open sores or ulcers, the simple or compound tincture of iodine will be most advantageously applied to them, in modes and in degrees of dilution varying with their appearances.
in the same individual. Experimenting upon apes, it was found that the artificial ulcers regularly diminished in size and virulence, in proportion as the inoculations were multiplied, until at length the virus ceased to take effect. The system seemed to become protected, as in ordinary inoculation and vaccination, and a state or diathesis was produced, in which the body was no longer capable of being affected by syphilis; and the process by which this is accomplished is that to which the name syphilisation belongs. This result, also, is all the more surprising because recent inoculated patients were evidently essential to it, for only once inoculated and then left to themselves, the poor apes speedily perished with all the signs of the syphilitic cachexy. Having satisfied himself of the reality of these results, M. Aurelii Tursunke then proceeded to enquire whether man was capable of syphilisation. He had many ardent followers, who eagerly submitted to the experiment, and who shortly seemed to furnish evidence in the affirmative.*

156. This pretension excited great opposition, particularly in the Académie de Médecine. In other words, the institution was more or less favourable. At Turin, M. Casimiro Sperino, the chief surgeon in the Syphilicomia, or Syphilitic Hospital of that city, at once took up the new views, and put them to the test on a large scale. He was favourably inclined towards them, he tells us, for several reasons. He had observed that severe inguinal buboes are more apt to follow small and insignificant chancrens, which heal in a few days, than those which are large and obstinate; that the constitutional symptoms held an almost inverse relation to the severity and continuance of the local disease; and that he had known many prostitutes, whose constitutions had never been sensibly affected, who had had chancrens for years, either constantly open, or closed only to open again immediately. He had repeatedly satisfied himself that foul buboes were more prone to heal in those cases in which their syphilis chancres had been tested, after Ricco's plan, by inoculations on the surrounding skin.

157. The subjects of M. Sperino's experiments were fifty-two hospital patients, all prostitutes, and all suffering from aggravated forms of primary or secondary syphilis. The virus was taken from the proper syphilitis, or from a comrade— from the first, if possible—and always from a growing ulcer. The inoculations were repeated once or twice a week in three or four distinct places, usually in the abdomen. The time required for the establishment of the artificial chancrens was from two to three days. The effects of the second inoculations were less serious than the first, of the third, than the second, of the fourth than the third, and so on until the virus ceased to produce any effect whatever; contemporaneously with which epoch, all former ulcers had healed, and buboes, recent nodular enlargement of bones, and cutaneous sores or blotches had either disappeared, or were in rapid process of disappearance. The virus, also, which made no impression at this time, was found to retain all its virulence when tried upon an unprotected person.

158. Since this time M. Sperino has shortened the intervals between the several inoculations, and has increased the number of punctures in each operation to twelve, sixteen, or twenty, and with the effect (he tells us) of expediting the process, and of ensuring a slighter form of artificial chancre. He has also subjected his syphilitic patients to a course of bathing in the sulphurous waters of Acqui, which waters are notorious for their power of bringing out secondary symptoms in the subjects of syphilis, and he has found them to resist this test as well as that of inoculation.

159. Such are the main particulars of these fifty-two cases, as gathered from M. Sperino's communication to the Academy of Medicine and Surgery at Turin. No other treatment was employed. They are said to have been without exception of an aggravated character, and without any spontaneous tendency to heal. For a month before their cure was declared, they had been purposely left without any treatment, and during this period they had retrograded.

160. An account of Dr. Sperino's proceeding was given by Dr. Racelis (in Rakeis's Abstract of the Medical Sciences, vol. xvi. p. 333.), and M. Tursunke's experiments were noticed by Dr. De Merce (Lancet, July, 1853, p. 203.) before Dr. Sperino's work had appeared. The subject has been very recently brought before the profession in an able article on syphilisation in the British and Foreign Medical-Chirurgical Review, (No. xlviii. p. 410.), in which the subsequent experience of Dr. Sperino in Turin, of Professor Boer in Christiana, of Dr. Danielson in Berge, and of Dr. Carlsson in Stockholm, during several years has been given. These enlightened men, professors and physicians to hospitals in cities where medical science is in its highest state of rational cultivation, have been engaged in a series of careful experiments and observations to determine its truth or its fallacy. Experiment and careful observation can alone decide this question, which is one of the greatest importance in practical medicine.

161. Dr. Sperino's observations were confirmed by similar results obtained by Dr. Gambrini at Bologna, and by Dr. Guilio at Florence. In 1853, Dr. Sperino published a detailed account of ninety-six cases of syphilisation. Of these ninety-six cases, fifty-three were of primary syphilis, and forty-three of the constitutional disease. Fifty of the cases of primary syphilis were cured, two failed, and one was not treated by syphilisation alone. Of the forty-three cases of constitutional affection, twenty-six were treated by syphilisation alone, and seventeen by this method, in conjunction with mercury or iodine. Twenty-five of the twenty-six in the first category are said to have been cured. In only two cases of the primary disease did any constitutional symptoms appear, and these symptoms rapidly yielded under a continuance of the syphilisation. No relapse has yet taken place in any case. Many of these cases were of very late character, and were such as were not likely to have healed spontaneously; while the numerous

* In Dr. Winterbottom's work on the native Africans already referred to, it is stated, on the authority of Mr. Fox, in the Appendix to the History of the West Indies, that the natives of the Gold Coast of Africa give their children a grain by inoculation; and that they perform the operation by making an incision in the thigh, and inserting some of the matter from the sores of the young syphilitics; however, the impression or children have the disease slightly and recovered speedily; whereas, by becoming infected at a later time of life, it is much more severe, and "gets into the bone." (Vol. ii. p. 155.)
Inoculations that were required, produced no serious effects, except in one or two instances a slight tendency to form phagedenie sores.

162. Dr. Boeck of Christiansia, in 1853, published, in the seventh volume of the Norwegian Medical Journal, the results of a few experiments he had then made on syphilisation. Since then he has closely investigated the subject, and does not consider extended the practice to infants at the breast. The same plan of treatment has also been pursued by Dr. DanielSEN in the hospital at Bergen. When the writer of the review above referred to (§§ 160.) re-visited this hospital in July 1856, he was assured by this physician "that he fully coincided with the views of Dr. Boeck, and that the results obtained in Bergen by syphilisation were as successful as those recorded by the latter at Christiansa." The reputation, talents, and high position of those physicians in Norway are unquestionable.

163. Dr. Boeck states that all the cases which he treated by syphilisation, and which had undergone a mercurial treatment, persons of an inflammatory diathesis, habitual spirit drinkers, and weakly constitutions, should not be subjected to this treatment. In these cases the artificial chancres may take on a malignant action. "The bowels should be regulated, and the digestive organs brought into good order; but it is not necessary to enforce any strict rule of diet. In the hospitals of Bergen and Christiansa, the ordinary full diet was always allowed." Dr. Sperino and Dr. Boeck mention the readiness with which persons are subjected to, and even sought for, the mode of cure which they had seen so successful with their fellow sufferers.

164. M. A. Turenne at first kept up a succession of single chancres; while Sperino made three or four separate inoculations at once, and repeated these two or three times in the week. After having in this way reached twenty-four or thirty inoculations in all, he found that the chancre last produced were exceedingly small, and he then diminished the intervals, and made more inoculations at each sitting. He found that the first chancres were deeper, larger, and more inflamed than those which succeeded them: and that by diminishing the intervals and increasing the number of inoculations the earliest chancres visibly diminished, and were less painful and inflamed. After a large number of inoculations which did not appear successful, he returned to his former plan of inoculating for six to ten chancres at a sitting. "While these chancres are progressing, it is not advisable to inoculate afresh, nor should this be done until the former chancres are developed. Should the chancres he developed too freely and threaten active inflammation, or to extend as phagedenie sores, he checks their progress by inoculating afresh at shorter intervals." 165.

The practice of Dr. Boeck differs little from that of Sperino. He inoculates for two chancres only every six days, because he found from experience that it required about five days to produce induration in a chancr, although he considers it not absolutely essential. He subsequently shortened his intervals to three days, and increased the inoculations to eight or ten. Less time is thus required to produce immunity; but Dr. Boeck is distrustful of pushing cases too rapidly through their course of syphilisation. With regard to the parts of the body selected by these physicians for inoculation, Sperino preferred the lower regions of the abdomen, Dr. Boeck the arms and thighs.

166. The conclusions drawn by Dr. Boeck from the eighty-four cases of syphilisation, which he has treated up to March, 1856, are,—1st, That in all cases, with or without constitutional syphilis, in its most varied stages and forms. Some of these cases had previously undergone every mode of treatment that science could devise, while others had had no treatment at all. He thought it of great importance to collect observations from both classes of cases. His syphilisation is not had recourse to till all other remedies have been tried, it is difficult to form a correct estimate of its powers; for under such circumstances, as Dr. Boeck justly remarks, we can hardly know what symptoms belong to syphilis, and what to the medicines administered; and particularly to mercury. He states, that cases which have undergone a mercurial treatment, persons of an inflammatory diathesis, habitual spirit drinkers, and weakly constitutions, should not be subjected to this treatment. In these cases the artificial chancres may take on a malignant action. "The bowels should be regulated, and the digestive organs brought into good order; but it is not necessary to enforce any strict rule of diet. In the hospitals of Bergen and Christiansa, the ordinary full diet was always allowed." Dr. Sperino and Dr. Boeck mention the readiness with which persons are subjected to, and even sought for, the mode of cure which they had seen so successful with their fellow sufferers.

167. The time required to produce immunity from syphilis by syphilisation depends upon the various strength of the virus, upon the rapidity or otherwise with which the inoculations succeed each other, upon the number of the chancres produced, and upon the idiosyncrasy of the patient. Dr. Boeck states that, "the attaining to immunity depends upon the length of the intervals between each inoculation—the more frequent the inoculation the more rapidly does it ensue. If there were sufficient virus to be obtained, we might, if we chose, inoculate every day; but in general the rule, we keep to obtaining the virus from the most recent inoculation, we cannot easily do this. From my own experience, I would say that the matter obtained in a pustule of only one day's growth is generally capable of being inoculated; but I have also seen that pustules of three days' growth produced no effect; while three days later, the matter taken from them was decidedly contagious." (p. 196.)

168. Granting that immunity is really produced from the disease, the question follows, Is it merely from the existing disease, or from any subsequent infection? and if from subsequent infection, is the immunity produced for a time only, becoming impaired gradually, and ultimately lost after an indefinite time; or is it continued through life, a diathesis being imparted by it, rendering the frame insusceptible of the syphilitic infection? That the immunity is of short duration is shown by the fact of the last inoculation having failed to take effect, however virulent the matter employed. Dr. Boeck is of opinion that persons who have reached perfect immunity to inoculation in the course of syphilisation are insured against contracting syphilis for all the rest of their
lives; but the lapse of time since the first employment of this practice admits not of any conclusive evidence of the fact.

169. Of forty-two cases of constitutional syphilitic fever, no mercury had been previously used, not one had exhibited any relapses up to the commencement of 1856, and many of these had been for three years or more without requiring any treatment whatever. Of the twenty-one cases recorded in Dr. Bozck's first work, six had been treated without mercury, and in all these syphilisation dispersed the symptoms, which have never returned. The average duration of the treatment in these six cases was six months and two days, the average number of chancres being 322. In a second class of cases, in which the constitutional symptoms were chiefly confined to the skin and mucous membranes, but which had all taken more or less mercury, the average duration of treatment was six months and twenty-four days, the average number of chancres being 432; two thirds of the number being, however, very small and transient. In the third category of cases, in which the constitutional disease was very insignificant, and which had been subjected to mercurial treatment, some repeatedly, the average duration of treatment was seven months and twenty-four days, the average of chancres 570.

170. The increase in both of the last categories of cases in the number of chancres, and in the length of time required to complete the cure, is ascribed by Dr. Bozck to the previous administration of mercury. It is, however, probable, as he observes, that another circumstance may have retarded the cure, viz., that the syphilitic virus may have undergone a material change during the many years it had been resident in the system. The more inveterate, and especially the tuberculo-serpiginous forms were found to be extremely rebellious to treatment, and some of them were not cured when immunity was reached. It was necessary then to have recourse to iodine, upon the exhibition of which all symptoms rapidly disappeared, though Morbus Gallicus, in quo quidem Celeritatis in Tali Materia Scribita Medicum Continente Anteera, syo. Venetiis, 1525. — P. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530. — H. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530. — H. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530. — H. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530. — H. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530. — H. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530. — H. F. de Brackenbury, Neugrae eae Tractatus de Morbo Gallico, Libri duo, 1530.

171. Dr. Bozck suspects that in those very obstinate cases an union of the syphilitic with mercurial poison has taken place. In most instances this seems to be dissolved by syphilisation, and then iodine, which had been before ineffectual against the united poisons, acts readily on the mercury, and eradicates it from the system. During the two years elapsed from the publication of his first work, he had treated sixty-three cases by syphilisation, and of these thirty-six had never taken mercury. In the twenty-seven cases, for which mercury had been given, he invariably found the cure more difficult, and in some cases impossible without the aid of iodine. Where mercury has not been employed, he is decidedly in favour of syphilisation, for, as far as he can ascertain from the forty-two cases of this character thus treated, no case where no mercury had been found the cure more difficult, and in some cases impossible without the aid of iodine. Where mercury has not been employed, he is decidedly in favour of syphilisation, for, as far as he can ascertain from the forty-two cases of this character thus treated, no case where no mercury had been given, has failed of a cure. A great objection to syphilisation is the length of time required for its complete performance. In the Christiana hospital, the average duration of the mercurial cure is three months and a half, while syphilisation averages a full half year. If, however, the latter is not liable to relapses, as in at least in some mercurialised cases, it is preferable even if it required a much longer period. It is doubt-

VERTIGO—DESCRIPTION OF.

Vertigo—Syn.—Vertigo (from vert, I turn round); περιτροπή, πτωτάμα. Vertige, Fr.; der Scheuqnel, Germ. Giddiness, dizziness, swimming in the head.

CLASS.—IV. Class. III. Order (Author).

1. Defin.—A transitory erroneous perception, or a sense of general whirling or turning round, with difficulty of standing, or a feeling of impending sinking or falling.

2. Vertigo has been noticed by Hippocrates, Galen, Aretaeus, and other ancient writers; and, by these, as well as by modern writers, it has been viewed chiefly as a symptom of many diseases, and in some, in much rarer cases, as the chief or only apparent disorder. Thus, in 6th, in 5th, in 4th, or several other disorders, may be admitted, although it may be shown, if the pathogeny of the affection be duly considered, that it is commonly owing to previous disorder of the organic nervous influence endowing the brain, or to the state of the capillary circulation in this organ; or, not improbably to both in various degrees. In the great majority of cases, however, it is merely a symptom, either of a very early, or of a more or less advanced stage of some malady, very often of some disease which has not fully declared itself, or which still remains latent or imperfectly developed, or of extreme debility, or of protracted indigestion, &c.

3. I. Description.—Vertigo occurs as an illusion, or a transitory erroneous perception of objects, although quiescent, in a state of more or less rapid motion, usually in that of gyration or whirling round; but also not infrequently with either a descending or ascending movement, or with a sense of sinking. In the more extreme cases, or when caused by ebriety, these sensations are often present in a greater or less degree, although the eyes at the time are quite shut. In some instances the objects which thus appear in motion are also changed in colour — are either variegated or obscured. Vertigo may be experienced only when assuming the erect posture, as in cases of fever, extreme debility, &c.; but it may also be felt whilst recumbent in bed, objects presenting not only a rotary, but also an ascending motion, with a feeling of sinking, and sometimes also with noises in the ears. In this latter form it should be viewed as a most serious symptom, especially when occurring in malignant or pestilential maladies, or when these are prevalent, or in the course of organic disease of the brain. In many instances, vertigo precedes, or is followed by severe paroxysms of retchings or of vomitings. This sequence is commonly observed in pestilential choler, in sea-sickness, in fits of drunkenness, after ingestion of the sedative or depressing and irritating poisons, and especially after the improper or inordinate use of tobacco. In all cases of vertigo, walking or even standing is difficult or impossible; and from a dread of falling, objects are laid hold of for support. Vertigo may be only temporary and quickly evanescence, or it may continue for a considerable time. It is more rarely continued or prolonged. It is often evanescent, but marked, when it occurs as a prelude of syncope, or of fully developed disease of the brain, as epilepsy, paralysis, or apoplexy. In cases which precedes dementia and other states of insanity, Swift was very subject to vertigo at different periods of his life, and more especially before the loss of his powerful mental faculties. It is more prolonged or continued when it is a symptom of either active or passive congestion of the cerebral vessels, or of anaemia of the brain, or of the vascular system generally. When vertigo occurs as a severe or acute paroxysm, it may gradually pass into the epileptic state; the extreme giddiness, after several occurrences of the seizure, being attended by a temporary loss of consciousness, and ultimately by convulsions and all the phenomena of a complete epileptic attack.

4. The more continued or prolonged states of vertigo are generally referrible to the following pathological conditions: — 1st, To determination of the blood to the head, due to congestion of blood in the cerebral vessels, owing to impeded return of blood or retarded circulation through the heart; 2d, to lesions of the cerebral arteries, and softening of the structure of the brain; 3d, to general or local, momentary or prolonged, anaemia, or insufficient supply or circulation of blood in the brain. In these states, however, one or other of the primary changes already assigned as characterising the more evanescent states of the affection (§§ 3.) are also present. In either of these forms, or owing to either of their pathological states, vertigo may manifest certain grades, either of which only may be complained of, or all of which may supervene in succession, either very slowly and imperceptibly, or more or less rapidly. These states or grades are usually described as — 1st, confusion, unsteadiness, or indistinctness of perception; — 2d, dizziness or fear of falling; — 3d, giddiness, with impeded return of blood from the recumbent posture, long abstinence, inanition, and, in short, whatever occasions too great fullness, on the one hand, or too great a deficiency of blood in the brain on the other, will, in weak, susceptible, or predisposed persons, give rise to this state of morbid perception.

5. i. The occasional exciting causes of vertigo are very different, or even opposite in different cases. Whatever determines the blood inordinately to the brain, as, long and intense thought and reflection,—or prevents or impedes the return of blood from this quarter, as, cinures, of the neck, &c.; and whatever promotes a rapid return of blood from the brain, as, suddenly assuming the erect from the recumbent posture, long abstinence, inanition, and, in short, whatever occasions too great fullness, on the one hand, or too great a deficiency of blood in the brain on the other, will, in weak, susceptible, or predisposed persons, give rise to this state of morbid perception.

6. Vertigo is most frequent in persons of advanced age, in hysterical females, in persons who are bald, especially on exposure to cold, or in cold seasons and in variable weather; in those liable to hemmorhoids, epistaxis, or other hemmorhages, especially when these are suppressed, and in crowded and close apartments; in females during prolonged lactation; in persons addicted to excessive sexual intercourse, or to the vice of
mysturbation; and in those who indulge in too much sleep or who lie too long in bed, or who live irregularly as to diet and regimen.

7. The more common causes of vertigo are obviously those which produce the diseases of which vertigo is a more or less prominent symptom; whilst those occurrences of it which assume more of a primary or idiopathic form, are referable entirely to whatever occasions the pathological states of which it is a chief manifestation. Thus, if it be imputed to vascular determination to, or congestion of blood in, the brain, the numerous remote and efficient causes of these conditions should be ascertained, as indicating the only obvious means of removing the affection. If it be chronic, protracted, or of frequent recurrence, the temperature of the scalp, the state of the arterial and venous circulation in the neck, temples, &c., the circulation through the heart; the functions of the stomach, bowels, and kidneys, &c., severally require examination, especially with reference to excessive or to deficient fulness of blood in the vessels of the brain. The causes of these very opposite conditions are generally manifest, on due investigation; but a portion are commonly attended by others of not less importance, namely, by excited, or by depressed vital power — by the latter especially. This association of disordered circulation with depressed vital power obtains in most cases of this affection, whether protracted or evanescent; and, in febrile diseases, the blood is also more or less altered, although not in a manifest degree at an early stage of these diseases. The impairment or depression of vital power is especially evinced by the organic nervous system, through the media of the several organs which this system endows, and more particularly of the digestive, assimilating, and generative organs. Impairment of the former, and exhaustion from abuse of the latter, are among the most efficient sources of this affection, in its more chronic forms. When it proceeds from this last source, the disorder is often most protracted, and most difficult to cure; for the cause generally continues, and it not infrequently assumes a recurrent or periodic form, and even ultimately, but gradually, passes into fully developed epilepsy, or the worst forms of hysteria. Of these results I have seen several instances in both sexes, in the course of my practice.

6. ii. The chief states and associations of Vertigo may be enumerated as follows, with reference to their causes: — 1st, Vertigo nervos: nervous, hysterical, epileptic, or hypochondriacal vertigo. 2d, Vertigo traumatica, from injury, conclusion, &c., of the brain. 3d, Vertigo phlebitis, from determination of blood to, or inflammation or active congestion of, the brain. 4th, Vertigo toxicata, from poisons, especially sedative and narcotic poisons, and from poisonous fish, meats, &c. (See Art. Poisons.) 5th, Vertigo febrilis, in the invasion and progress of most fevers, especially when the organic nervous force is depressed, and the brain excited; but this is not, Vertigo gastricae, from gastro-bilious disorder; such disorder, however, often being, as well as the vertigo, merely symptomatic of disease of the brain. 7th, Vertigo exanguinans, from an insufficient supply of blood to the brain, or from general anaemia, or unequal distribution of blood. 8th, Vertigo haemorragica, from disease of the heart impeding the return of blood from the brain. 9th, Vertigo arthrithica, from misplaced or retro-cedent gout. 10th, Vertigo rheumatica, from rheumatisation of the membranes of the brain, or of the pericranium. 11th, Vertigo accidentalis vel fugans, from various odours or noxious gases, in certain idiosyncrasies, or from various causes, often of an indefinite or not very manifest nature.

9. iii. The diagnosis and morbid relations of Vertigo. — The nature of the affection is generally manifest from the account given by the patient of his sensations. It may, however, in the more sudden attacks, be mistaken for a slight seirure of either apoplexy or epilepsy. From both these it may be readily distinguished by the loss of consciousness, which does not occur in vertigo. When fits of vertigo are likely to pass into epilepsy, a momentary loss of recollection or consciousness then generally characterises them. The difficulty in the diagnosis respects chiefly the pathological condition of which vertigo is a chief or related manifestation — as regards the states of organic nervous or vital power, and of vascular action or congestion in the brain — as to the affection being a passion is commonly attended by others of not less importance, namely, by excited, or by depressed vital power — by the latter especially. This association of disordered circulation with depressed vital power obtains in most cases of this affection, whether protracted or evanescent; and, in febrile diseases, the blood is also more or less altered, although not in a manifest degree at an early stage of these diseases. The impairment or depression of vital power is especially evinced by the organic nervous system, through the media of the several organs which this system endows, and more particularly of the digestive, assimilating, and generative organs. Impairment of the former, and exhaustion from abuse of the latter, are among the most efficient sources of this affection, in its more chronic forms. When it proceeds from this last source, the disorder is often most protracted, and most difficult to cure; for the cause generally continues, and it not infrequently assumes a recurrent or periodic form, and even ultimately, but gradually, passes into fully developed epilepsy, or the worst forms of hysteria. Of these results I have seen several instances in both sexes, in the course of my practice.

10. There are other circumstances than the above to which attention should be directed; and amongst these the probable existing morbid states causing this affection at different periods of life may be noticed. If the disorder occurs soon after, or even several years after, puberty — and if the patient be thin, pallid, or anemic, and be incapable of directing his eyes firmly on the person addressing him, impaired nervous power, very probably occasioned by mysturbation, may be inferred. If the affection occur in mature or advanced age, although it may proceed from disorder of the digestive organs, it may, as well as such disorder, be much more likely a prominent symptom of disordered circulation in the brain, caused either by atheromatous, fatty, ossific, or other changes in the coats of the arteries, or by disease of the heart, of its valves, or even by organic lesion of the intima structure, or by more manifest alterations of the brain, either consequent upon one or other of these causes, or of the vessels, or taking place independently of them. I have seen cases where this affection has been produced by these several lesions, by scrofulous, tubercular, cancerous, or other formations in the membranes or substance of the brain, and by impeded return of blood from the head. In a recent and curable case of colloid cancer of the mamma, under
my case a few years ago, that was seen by Dr. Ramsbotham and Mr. Ferguson, the coccus disease ultimately invaded the brain, occasioning, for a considerable period, constant vertigo, and ultimately general paralysis and coma. The connection also of vertigo with jaundice, and the occurrence of it as a form of misplaced gout, should not be overlooked when it affects persons of mature or advanced age, especially when the exact nature of the affection is clinically investigated. The connection of this affection also with cachetic states of the system, with imperfect excretion and depuration of the blood, and with disordered function or organic lesions of the kidneys, but still more intimately with organic lesions of the heart, its orifices, or of its valves, demands due consideration. Several instances of chronic vertigo have come before me which had been referred to cerebral disease, but which, upon auscultation of the heart, were found to depend upon impeded return of blood from the head, owing to interrupted circulation through the heart.

11. THE PROGNOSIS of vertigo should be always given with caution, and often with much reservation. In some cases, especially in early or more transient stages; but in the great majority of cases it depends chiefly on disorder of the digestive organs, or the organic nervous system, a favourable opinion may generally be given, unless there be reasons to infer that it is a precursor of fever of an exanthematosus or any other form; and then the result will entirely depend upon the consecutive disease. Whenever the affection occurs suddenly or in fits, then its passage into fully developed epilepsy should be dreaded, however judicious the treatment may be, more especially if there be any reason to infer that it is caused by masturbation, or by excessive venereal indulgences. Of this causation and transition of vertigo, many cases have come under my observation, not only in early and middle, but also in far advanced age. In this last period of life, as well as in middle and mature age, vertigo, in any of its grades, should always be dreaded and viewed as a precursor of a more serious or terminal attack. In these cases the symptoms connected with the organs contained within the cranium should be carefully observed, especially the several senses; the temperature of the scalp, the state of the pulse in the carotids; the action, rhythm, and sounds of the heart, and the appearance of the veins of the head and neck, and an opinion be given conformably with the evidence furnished by these sources, the juvanta and lassitude of many being also taken into due consideration.

12. III. THE TREATMENT should be based upon the inferences arrived at as to the causes and pathologial states of vertigo. — (a.) If the causes inferred be such as reduce organic, nervous, or constitutional power, and if they are of such a nature as are likely to convert the disorder into either hysterical or epileptical seizures, as certain of the causes above noticed (§§ 6, et seq.), a restorative, tonic treatment, such as the preparation of valerian, saffoatida, zinc, &c., cod-liver oil, oxtre of silver, &c., ought to be prescribed; and if there be any indications at the same time of local or general anaemia, chalybeates, either alone or in addition to these means, are also required. In cases of this description, as well as in those indicating a tendency to assume either an hysterical or epileptic character, I have found the tincture of sambul, either alone or conjoined with other medicines of a tonic or antispasmodic nature, of great service in several cases. In these also I have prescribed the atropinoid unctuosity, but not with so marked benefit as I expected, although it was sometimes very beneficial.

13. (a.) In persons who are liable to vertigo from prolonged or profound thought and reflection (§ 5.), and especially if the scalp be hot and vascular determination to the brain, as evinced by the action of the carotids, be excessive, cooling applications to the brain, local depletions, internal and external derivations, purgatives, a regulated diet, and, above all, the avoidance of the cause, change of air, of scene, and of habits, travelling, voyaging, &c., and relaxing amusements, or agreeable and slight occupations merely, are the means upon which the chief reliance should be placed.

14. (a.) In persons of a full habit of body, in those who live luxuriously, or even moderately, and who take little exercise, the temperature of the scalp, the pulsation of the carotids, or the action or sound of the carotids in the temple and in the local or general plethora, or impeded return of blood from the head, the occurrence of vertigo should be viewed in a very serious manner, and local depletions, derivations, both external and internal, purgatives, scions, or issues, sparse diet, and regular exercise in the open air are generally beneficial. Other means in addition to these may be resorted to; but they must be left to the judgment of the physician, who will prescribe them appropriately to the features characterising individual cases. Emetics, the application of cold to the head, the restoration of suppressed hemorrhages, bleeding from the nostrils, and venesection, were the chief means recommended by Aretaeus for vertigo, and they are indicated in the circumstances just now mentioned; but emetics should follow, not precede, the other means when cerebral or general vascular plethora is present.

15. (d.) In cachetic habits of body, in cases manifestly depending upon disorder of the digestive organs, and when the temperature of the scalp, and the local and general states of the circulation and of vascular action, present no contra-indication of the propriety of the practice, the treatment of vertigo may be initiated by the exhibition of an emetic. When this affection is indicative of the commencement of fever, or of one of the exanthemata, and is attended by lassitude, pains in the back or limbs, or by chills or shivering, this practice is then also procreative of benefit; but ipecacuanha or sulphate of zinc should be preferred to antimony, as an emetic; or, if this last be prescribed, it will be advantageously conjoined with a warm, aromatic, or antispasmodic medicine, such as Cayenne, ginger, &c.; but it ought not to be repeated oftener than once. Vertigo in the stomach, as it requires, in the first instance, cholagogue purgatives followed by all alkalis, magnesia, sulphur, and other vascular depurants, which increase the functions of the kidneys, skin, and digestive mucous surface. In all cases of vertigo unconnected with the invasion of either of the forms of fever, the previous habits, modes of living, and disorders of the ge-
VOICE AND SPEECH—Disorders of.—1. Voice and speech are functions by means of which the human species claims and maintains an ascendency over all animated nature. The more perfect animals, including the winged creation, possess the power of emitting vocal sounds, which admit of such changes in power, modulation, and character, as convey intonations to individuals of their own genus or species of danger, of pleasure, of sources of nourishment, of desire, and even of affection. Man, far more so than any other animal, can recognise, in nearly all animals which emit sounds, variations in cadence, character, and power, which are known by the same species as announcements of the presence of objects of prey and subsistence, of sources of danger, of the loss of offspring or objects of affection, affecting the welfare, safety, and distress. And it is by no means improbable, that the sounds characteristic of individual species, even of the lowest capable of emitting them, are so modulated as to convey to one another the various instincts and suggestions, which springs, localities, and external circumstances and influences, may excite; the sounds thus modulated becoming, as regards each species, their distinct, but limited language, although unknown, unless in its more manifest and prominent characters, to man.

2. The sounds produced by the organs, as wonderfully and beautifully provided for them, is the human species, is the chief means of developing the mental faculties, of exercising dominion over the rest of the animal creation, and of acquiring and of exerting power over those requiring guidance or governance. The sounds produced by the human organs of vocalization and articulation are the manifestations furnished to the species of the finest sentiments, of the deepest as well as all the highest states of feeling, of the most profound and abstract results of thought, and the wisest and best revelations of mental reflection and of human reason. But considered philosophically, they are studies rather for the physiologist than for the pathologist. In the latter, however, the more strictly considered use of human sounds, as manifested in the modulated voice and in speech, becomes a necessary introduction to an intimate knowledge of the several modes in which both voice and speech are disordered, or more or less impeded, or even lost. For these preliminary sources of knowledge the reader is referred to the recent writings of Müller, Carpenter, Todd and Bowman, Bishop and Willis, which are in the hands of most medical men.

3. Vocal sounds and articulate speech or language are two distinct functions; and although the latter proceeds from the former, an additional apparatus is required for its production. The instrument of vocal sound, the larynx, is distinct and appropriate to this purpose, and is calculated by its mechanism to produce the several grades and modulations of voice; but, although thus independent, the vocal sounds cannot be modified into articulate speech, or even into a near approach to articulation, without the aid of the oral cavity, more especially of the tongue. Hence there may be vocal sound without speech; but this latter cannot be produced without the former; and both hence may be separately or even conjointly disordered, or even lost. But, although speech may be altogether lost, a vocal sound can hardly be quite lost whilst respiration is performed, unless in complete syncope, catalepsy, apoplexy, in the coma of fever, and in other occasions of loss of sensibility and consciousness; for even in these states, unless in profound syncope and catalepsy, a simple or low respiratory sound may still be emitted.

4. 1. Voice is produced, according to Mr. Bowzer, by the conformation of the vocal apparatus, by which the larynx, which combines the properties of a stretched chord, a membranous pipe with a column of air vibrating in it, and a reed, and is the perfect type, of which these instruments are only imperfect adaptations. Dr. Carpenter states, "that the sound is the result of the vibrations of the vocal ligaments, whichever, suffering, ordering to the same laws with those of metallic or other elastic substances; and that the pitch of the notes is chiefly governed by the tension of these lamine." However, the
various tones, modulations, &c. of the voice may be explained, or referred severally to the especial or combined movements and actions of the different parts constituting the vocal apparatus by physiological writers, it must be manifest that a healthy condition of the vocal chords and ligaments, of the cartilages, of the muscles which move and sound all of the parts both above and below the larynx, as well as of the larynx itself, and the mucous membrane covering it and its vicinity, and even of the velum palati also, is necessary to the production of the human voice in its natural and perfect state; and consequently that this function, capable of the utmost perfection, of the greatest range in power and modulation, and of astonishing improvement as regards these, by careful and scientific cultivation, depends upon a perfect condition of these several parts, disorder or structural lesion of any one of them affecting the voice in a more or less remarkable manner.

5. Disease of the vocal apparatus, or complete or partial loss of the power of emitting vocal sound, owing either to functional disorder or to structural lesion.

6. The voice may be impaired in every degree from the slightest catarrhal form to the most complete loss from organic change. The impairment or loss may be either temporary or permanent. The slightest as well as the least permanent aphonia often proceeds from functional disorder, especially from extreme nervousness, fright, fear, and hysteria; but it also is frequently caused by catarrhal congestion of the mucous membrane of the larynx and of the subjacent cellular tissue, and by temporary impediment to the movements of the vocal chords from this cause, or from inflammation and its results implicating for a time any of the parts of the vocal apparatus. In the more strictly nervous states of aphonia there is no manifest lesion of structure, the nerves supplying the laryngeal muscles and chords having become for a time apathetic, of the consequence being the deficit of volition to these parts, unless volition be most energetically exerted.

7. A. Functional Aphonia occurs chiefly in delicate, nervous, or hysterical females, and much more rarely in similarly constituted males. In the former sex it is most frequent about and subsequent to the period of puberty, and during the catamenial epoch of life; in the latter chiefly before the period of puberty, and only in very rare cases, and when occasioned by fear or fright, and it is then of short duration only.

8. Hysterical Aphonia may be viewed as one of the forms of functional paralysis, which not infrequently complicates disorder of the female organs, such disorder being generally either not otherwise manifested, or latent, or masked by some other affection. In most cases it is easy to distinguish the hysterical from all other forms of aphonia; other allied symptoms, the previous history of the case, the state of the uterine functions, the moral affections, impressions, and sentiments, which may have preceded the loss, &c., generally indicating its nature. It should not be overlooked that, in hysterical females, more especially in those most subject to uterine or sexual irritation, aphonia is sometimes feigned. In rare instances, also, it may be difficult to determine whether or no it is hysterical or owing to structural disease in or near to the base of the brain; and this difficulty is increased, 1st, by the absence of other hysterical symptoms, and, 2dly, by the presence of other states of cerebral palsy, the catamenial functions or organs having been previously disordered. I was recently called in consultation to a delicate nervous female, aged 16, who had menstruated irregularly and scantily, and was seized with incomplete hemiplegia and complete loss of voice; the muscles of the face not being affected. In this case it was difficult at first to determine whether the aphonia was hysterical or owing to some lesion within the cranium, causing also the hemiplegic affection. Their history and progress, however, generally elucidate the nature of these cases.

9. B. Structural Aphonia is caused, firstly, by changes implicating one or more of the parts composing, or in the immediate vicinity of, the vocal apparatus; and, secondly, by lesions at the origin or in the course of the nerves distributed to the laryngeal muscles and vocal chords. The slighter or more incomplete forms of aphonia are those of a catarrhal nature, arising from more or less congestion and tumefaction of the mucous and submucous tissues of the larynx and adjoining parts. Severe cases of aphonia are often occasioned by serous infiltration into the submucous tissue, with or without inflammation of the mucous membrane of the larynx and of its vicinity, in the direction either of the fauces or of the trachea, or of both. This serous infiltration may be slight, and continue only during the catarrhal attack, or it may be so very considerable as to nearly suppress the voice altogether and cause suffocation, as observed in edema of the glottis and epiglottis. Aphonia from this and other affections of the vocal apparatus is fully considered in the articles Larynx and Trachea, where the lesions which affect the voice are described, and the treatment appropriate to each pointed out. The voice may also be affected in a typhus fever, and in epidemic cholera, pneumonia, smallpox, measles, and other diseases. In all cases, the voice often remains impaired after the disease is recovered from, and may be rendered permanently faint and husky. In some cases the voice becomes softer and gentler, the pitch lowered.

11. Voice, as stated above, is produced by the larynx, its modulations into musical sounds, &c.,
affected by means of this organ sided by the epiglottis and adjoining parts. Speech is the modification of the voice, or sounds emitted by the larynx, by the organs or parts intervening between it and the os externum. It is obvious that, to produce articulate sounds, forming language, the movements of the tongue, faucets, and connected parts must be complete; and that these should be in a healthy condition to render articulation perfect.

The tones of the voice, and articulate speech, cannot be produced in childhood, when the sense of hearing is completely lost in early infancy, or in the fetal state; and as long as the sense of hearing continues lost, dumbness is the result; for the sense required to modify and adjust vocal sounds does not exist.*

Voice, especially in its healthy and cultivated states, and in its modulations into music, is capable of expressing the several emotions of mind, in a more remarkable degree, and manner than articulate speech; but speech or language has a much greater, more varied, and more extensive power of addressing, informing, and enriching the intellect, of furnishing definite ideas of objects, properties, actions, &c., and of conveying the results of reflection and of rational deductions. The vocal organs, as well as the larynx, the tongue and parts composing the oral cavity, are adapted for, and in health is capable of, forming a number of simple sounds, which are readily combined into groups forming words. Dr. Carpenter justly remarks, that the number of combinations which can be thus produced is so inexhaustible that every language has its own peculiar series; no difficulty being found in forming new ones to express new ideas. There is much diversity in different languages, even with regard to the use of the simplest of these combinations; some of them are more easy of formation than others, and these accordingly enter into the composition of all languages; whilst, of the more difficult ones, some are employed in one language, some in another; no one language possessing them all, or using them to any co-ordinate extent.

12. The mechanism producing vocal sounds being complicated, and actuated in its individual parts, in its combination, or modification, and by the state of vital forces, as influenced by health, constitution, and disease, and adjusted by the sense of hearing, it necessarily follows that the faculty of speech, in whatever language, will be modified, altered, interrupted, impeded, and even altogether lost, in numerous modes, so as not only to furnish most important indications of disease of the slightest as well as of the most dangerous nature. The articulate sounds which have become familiar to the ear, are often remembered as long as the appearance of the person by whom they were furnished; and the person, even after many years, is often recognized by his voice and speech before he is seen. Deliberate weakens the articulating power, or the strength of articulate sound; but disease may alter it more remarkably, different maladies affecting it in various ways. When the voice is altered, or lost by disease, the speech is then necessarily similarly circumstanced, as already stated (§§ 5. et seq.).

But speech is more especially affected as a precursor, or as a symptom, of apoplexy and paralysis; and, when so affected, it indicates the most serious results at a period, which, although indefinite, may generally be viewed as comparatively short. In cases where speech is altogether lost, especially at an advanced age, or is so nearly lost as hardly to be understood, or when the sounds are mostly inarticulate, if no apoplectic or paralytic seizure have preceded or accompanied the loss, then either of these seizures may be expected before a long time elapse, unless the time be deferred by treatment of the diet, and regimen; and more frequently, notwithstanding these means of prevention (see arts. Apoplexy and Paralysis).

13. Loss of speech, whether complete or incomplete, is generally to be imputed to structural disease, wounds, or fractures, implicating either parts within the cranium, or the nerves in their course to the organs of articulation. Cases of loss of speech, consequent upon apoplexy, or associated with other paralytic states, are very frequent, and are by no means rare as a precursor of a dangerous apoplectic or paralytic attack. When the present, as the only apparent ailment, the result is not the less to be dreaded. In several cases, for which I have been consulted in the course of my practice, speech was so completely lost, that articulate sound was produced, the simple vowel sound a and a being only emitted, and yet none of the organic, or of the cerebro-spinal functions, and none of the senses, evinced any disorder. In these cases, an apoplectic or paralytic seizure supervised generally in a few weeks or months, owing to the development of latent pre-existing organic lesion. Whenever, therefore, the faculty of speech becomes impaired, or is lost by persons who had previously possessed this faculty in a healthy state, more especially if this change occur in mature, middle, or advanced age, it should be viewed as a form of local or partial paralysis, which is generally followed, at a very remote period, by a very dangerous form of apoplectic, or of more general paralytic seizure.

14. III. Impediments of Speech—Habitations of Speech—Stammering—Stuttering—This affection is generally functional, or of a nervous nature; and may present several forms. These are usually observed in childhood and is early life; whilst incomplete or complete loss of speech, briefly considered above (§§ 13. et seq.), is the consequence of a voice of injury, and is a form of paralysis of a dangerous nature. Habitations in articulating sounds, or a momentary impediment in uttering certain words or letters, or a stammering, or repetition of certain consonants, are generally observed from
infancy or childhood, but they may increase or diminish, or even disappear as age advances. They may continue during a long life, or they may occur only occasionally. In this latter case, they are induced or aggravated by fear, anxiety, and various mental emotions. They cannot be mistaken for impairment or loss of the previously healthy powers of articulate language, which, as stated above, proceeds from slowly-formed organic lesions implicating the organs or course of the glottis-pharyngeal nerves; and which occurs under different circumstances, and is attended and followed by very different phenomena and consequences.

15. The muscles employed in the production of definite vocal sounds and of articulate speech, being actuated by volition conveyed from the brain to these muscles by means of the nerves proceeding from the former to the latter, it necessarily follows that both voice and speech depend on the capability of the brain to generate or exert volition, and of the nerves to convey this act to the muscles. Thus speech, as well as voice, requires for its perfection a due exertion, and a healthy transmission of volition, by means of the nerves, to the apparatus destined to its production; and, if volition be feebly exerted, or imperfectly transmitted to the muscles concerned in articulation, various imperfections of these functions will result. But the complete performance of both voice and speech depends also upon the healthy functions of the lungs and respiratory passages, these functions being modulations of expiration by means of the larynx, tongue, faucial, oral cavity, and lips.

16. Thus it is apparent, as remarked by Mr. Bisshor, that "the mechanism provided for the production of speech comprehends a large assemblage of organs. The most simple vocal sounds require the combined action of the lungs, wind-pipe, larynx, and respiratory muscles; and for articulate language, an additional set of organs must be called into play, namely, the pharynx, hard and soft palates, uvula, tongue, teeth, lips, and nostrils."

17. It is justly observed by Dr. Carpenter that, "great as is the number of muscles employed in the production of definite vocal sounds, the manner in which their individual peculiar functions are combined, and the varieties of combination which we are continually forming unconsciously to ourselves, would not be suspected, without a minute analysis of the separate actions. Thus, when we utter the explosive sounds (explosive consonants), we check the passage of air through the posterior nares, in the very act of articulating the letter; and yet this important movement commonly passes unseen. We must regard the power of forming the several articulate sounds and their simple combination, as so far resulting from intuition, that it can in general be more readily acquired by early practice than other actions of the same complexity; but we find that, among different races of men, there exist tendencies to the production of different sounds, which, though doubtless influenced in great degree by early habit (since we find that children, when first learning to talk, form their habits of vocalisation in great degree in accordance with the examples amidst which they are placed), are certainly also dependent in part upon congenital constitution, as we often see in the case of children among ourselves, who grow up with certain peculiarity of pronunciation, not thus derived from imitation, of which they do not seem able to divest themselves."

18. I must refer the reader to Mr. Bisshor for a notice of mechanical contrivances for the production of vocal sounds; but these can never sufficiently illustrate the combinations of voice or the production of articulation, or even our faculties show what it is that constitutes the essential character or distinction between the vowels, and on what part of the mechanism of the voice the vowel-sounds depend. These sounds, as well as those of the consonants, are formed by so slight changes in the relative position of the several parts of the complex organs of voice and speech, varying in accent and intonation so remarkably with the language, &c., as hardly to admit of any estimate. Mr. Bisshor observes that, "in the application of the theory of vowel-sounds to the mechanism of the human voice and speech, there are two hypotheses which would equally satisfy the conditions for their production artificially. The first is, that the glottis produces the primary, and the air in the pharynx, mouth, and nostrils, the secondary or vowel-quality pulsations. The second is, that the glottis produces the primary, and the membranes of the pharynx, mouth, and nostrils, produce the secondary pulsations of the air." Dr. Thomas Young observes, in respect of the first of these, that the "reflection of the sound from the various parts of the cavity of the mouth and nostrils, mixing at various intervals with the portions of vibrations directly proceeding from the larynx, must, according to the temporary form of the parts, variously affect the laws of the motion of the air in such vibration."

19. As to the second view, Mr. Bisshor remarks that, "we know by experience that the breath passing through the glottis is thrown into a certain state of vibration, and reaches the cavity of the mouth, which is already so disposed as to present a proper extent of its own membranes to the action of the breath. By these means the membranes are also made to vibrate, and these latter vibrations, coexistent with the original vibrations of the glottis, may generate the vocal sounds." Now the chief objections which may be offered to this view of articulate language; and the varieties of combination which we are continually forming unconsciously to ourselves, would not be suspected, without a minute analysis of the separate actions. Thus, when we utter the explosive sounds (explosive consonants), we check the passage of air through the posterior nares, in the very act of articulating the letter; and yet this important movement commonly passes unseen. We must regard the power of forming the several articulate sounds and their simple combination, as so far resulting from intuition, that it can in general be more readily acquired by early practice than other actions of the same complexity; but we find that, among different races of men, there exist tendencies to the production of different sounds, which, though doubtless influenced in great degree by early habit (since we find that children, when first learning to talk, form their habits of vocalisation in great degree in accordance with the examples amidst which they are placed), are certainly also dependent in part upon congenital constitution, as we often see in the case of children among ourselves, who grow up with certain peculiarities of pronunciation, not thus derived from imitation, of which they do not seem able to divest themselves."

20. Very great ignorance, some mischief, and no little discredit to medical science, have been too often displayed by the evocation in great degree in accordance with the examples amidst which they are placed), are certainly also dependent in part upon congenital constitution, as we often see in the case of children among ourselves, who grow up with certain peculiarities of pronunciation, not thus derived from imitation, of which they do not seem able to divest themselves."

4 § 2.
VOICE AND SPEECH—AFFECTIONS OF, DESCRIBED.

... order under consideration. It has been supposed by these meddles, with surpassing prof... of the vocal powers; the very fear that stammering will occur, particularly under circumstances which render it peculiarly annoying, is often sufficient to bring it on in a predisposed subject; and the tendency to consensual imitation sometimes occasions stammering in individuals (especially children) who never show the slightest tendency to it except when they witness the difficulty is others."

23. That one or more of the four conditions which I have stated to be chiefly concerned in the production of stammering actually exists, will appear from what is observed as to the manner in which timidity, fear, and anxiety affect these conditions, and, by thus affecting them, produce in many persons either stammering or stammering; although they are not subject to these disorders of articulation in other circumstances. On this topic Mr. Busor very correctly remarks:—"The emotions which arise in a person when he is about to address an audience, are often so overpowering that the voice loses its natural volume, becomes tremulous, and sometimes inaudible, the respiratory functions are irregular, the flow of ideas is impeded, and the organs perform their office so imperfectly, that he who is generally ready and fluent in conversation, hesitates, stammers, and cannot utter a single connected sentence. Now if persons, who at other times have a perfect voluntary control over the organs of voice and speech, partially lose it under the circumstances just mentioned, a fortiori those who have at all times an imperfect control over their articulation will, in similar states of feeling, and of their powers paralysed, and their speech more than usually defective."

24. But it is chiefly in childhood and boyhood, when the sensibility and the emotional susceptibility are greatest,—whilst the due co-ordination of those movements of the parts which contribute to correct articulation is either being formed, or is in the course of development, or only recently perfected,—that stammering either commences or is chiefly manifested. At these ages, and more especially in those children in whom the faculty of speech is slowly developed, or appears only at a later period than usual, the emotions are most likely to disturb the force of volition, and, with this disturbance, the normal exercise of the intellectual, the respiratory, the vocal, and the articulating functions.

25. Whatever may be the cause or nature of the changes in the brain corresponding to the several emotions, they are propagated to the medulla oblongata, and influence the action of the respiratory and the motor nerves of the face, throat, and tongue, as well as other nerves, and through them the muscles they supply. The emotions may thus occasion irregular actions of the parts concerned in articulation; 1st, by causing a momentary spasm or closure of the glottis, and thereby arresting all vocal sound; 2d, by causing irregular action, or by closing the larynx, the medulla oblongata, and the organs of pronunciation of letters and syllables which begin with guttural letters; 3d, by the irregular or spasmodic motion of the tongue, the dorum of this organ being carried backwards, or brought into contact with the palate, thereby affecting the lingua-dentata, lingua-palatata, and lingua-palata-
nasals, and syllables or words commencing with these letters; and 4th, by closing the lips and posterior nares, by affecting the pronunciation of the labials, and even also of all the other letters. An acute and experienced observer may readily detect the particular cause of obstruction,—whether the glottis, faucæ, the dorsum or tip of the tongue, or the lips. 26. IV. The Treatment of stammering must be based upon the result of observation as to the seat of difficulty, or obstruction in the organs of articulation. Dr. Ander proposes that all the words should be reached by a vocal intonation, in such a manner that there shall never be an entire stoppage of the breath. But the difficulty is often at the commencement of a word or sentence, especially when the glottis is spasmodically or irregularly affected; and, as Müller contends, this plan cannot do all that is required, as the impediment often occurs in the middle of words, although it may afford some benefit. The most important remedial means is that much insisted upon by Dr. Carpenter, and this is to study carefully the mechanism of the articulation of the difficult letters, and to practise their pronunciation, repeatedly, slowly, and analytically. *The patient would at first do well to practise sentences from which the explosive consonants are omitted; his chief difficulty, arising from the spasmodic suspension of the expiratory movement, being thus avoided. Having mastered these, he may pass on to others, in which the difficult letters are sparingly introduced; and may finally accustom himself to the use of ordinary language. One of the chief points to be aimed at is to make the patient feel that he has command over his muscles of articulation; and this is best done by gradually leading him from what he finds he can do, to that which he fears he cannot" (op. cit. p. 771.).

27. The circumstance of stammerers being often able to sing their words better than to speak them, has been explained by the supposition that, in singing, the glottis is kept open, so that there is less liability to its spasmodic action; but, in singing, the velum palati, and the other parts concerned in articulation, are also much less liable to interference by spasmodic contractions, being brought into less action than in articulation. The difference may, however, as Dr. Carpenter supposes, be due to the direction of the attention rather than the muscles of the larynx than to those of the mouth. One of the most obvious and important objects in the treatment of stammering is the prevention of any emotional disturbance during the act of speech; and this requires the exercise of the voluntary powers over the direction of the thoughts, in the following modes: 1st, To reduce mental emotion, by a daily, hourly habit of abstracting the mind from the subject of stammering, both while speaking and at other times. 2d, To avoid exciting mental emotion by attempting unnecessarily to read or speak, when the individual is conscious that he shall not be able to perform these actions without great distress; 3d, To subdue mental emotion, by taking advantage of any little artful means to escape from the necessity. If the artifice continues to be a successful one." Having mastered the articulation of the difficult letters, and of the words containing them, and having thus avoided or overcome mental emotion, the patient should practise reading and speaking aloud, slowly, and with due enunciation and intonation, and with a full and free respiration, never allowing the lungs to become too far exhausted of air. Due attention should also be paid to the digestive and excreting functions, and to the improvement of the organic nervous force and of the mental powers, by air, exercise, medical treatment, and diet. Frequent looking, speaking, and reading or reciting aloud such passages as interest the mental emotions, should be practised as soon as the patient has acquired a complete command over his articulation and over the difficulties which mental emotions have occasioned him.

VOMITING AND RETCHING

PATRILINE IN TREATMENT OF

The stomach, with or without retchings, generally symptomatic of visceral or of constitutional diseases, but sometimes occurring independently of them, or of any serious derangement.—Retching is an ineffectual effort to reject the contents of the stomach, or painful contractile efforts, either before its contents are evacuated, or afterwards, and when the stomach is empty.

2. Vomiting and Retching are subjects of great interest:—1st, As symptoms of disease;—2d, As a therapeutic indication;—and 3d, as a prominent manifestation, if not a primary or idiosyncratic state, of serious disorder. The first of these is considered in the article on SYMPTOMATICZ (§§ 130, et seq.), as well as in the history of the several forms of disease: the second is partially noticed under the head of THERAPEUTICS (§§ 40, 43, and 56.), and in the eighth class, and the third order of THERAPEUTICAL AGENTS. Before, therefore, I proceed briefly to consider vomiting as a chief and prominent affection,I shall notice the circumstances which appear mainly to require the artificial production of vomiting.

3. I. VOMITING AS A THERAPEUTICAL INDICATION AND AGENT has not, in the article just now referred to, owing to the scope and subject of that article, been considered so fully as its importance demands. It is more especially required when poisonous or injurious substances have been taken into the stomach; or when the stomach is overladen by food or drink to an hurtful amount, more particularly when either or both threaten to occasion asphyxia, or when the body is in any other stricture, or when these attacks actually result from these causes. In all such cases, the selection of the emetic should be suitable to the cause and nature of the evil produced; and always be so energetic as to produce a rapid and full effect.

A. Diseases of the respiratory passages, especially those attended by asphyxia, by suffocation, difficulty of breathing, by difficult expectoration, &c., are of vomiting, may be stated under the following heads:—

1. The contact of irritating, poisonous, or unhealthy substances irritates the ganglial nerves supplying the visceral coat of the stomach, and affect the cardiac ganglia and adjoining plexus. The morbid impression or irritation is conveyed by the sympathetic nerves through the vagus cord by the ramifications of the ganglial nerves to these parts, and is reflected thence, by the motor nerves of expiration, to the abdominal muscles, by which I intend a "reflex sympathy," and Dr. MARSHALL HALL subsequently designated a "reflex function."—§§ 31, 32, 33, &c., affect other parts of the body (as stated §§ 18, et seq.), are propagated to the splanchic plexes and plexuses of the stomach, and through them to the spinal cord, and are reflected; in a similar manner, by the motor nerves chiefly of expiration, to the abdominal and expiratory muscles. The vomiting which thus occurs I have denominated from reflex sympathys, because it is only towards the alimentary canal, or of any constant or necessary an effect as to warrant the application of a function. —§§ 31, impressions made on the sensory, or irritative, part, through the middle of the pneumo-gastric nerves, affect the ganglial centres, and either through these latter affect, also, in the way above stated, the spinal chord and motor nerves, &c., be more directly propagated to both the splanchic and to the motor muscles, and then, to refer to either of the above categories. They proceed from an impression of an irritating or depressing character—the latter more particularly, or of any constancy on the semilunar and other splanchic ganglia and plexuses, and products at expulsion of from the contents of the natural cavities, as performed by the muscles of expiration, and whilst the ganglia are relaxed and laid open upon the lungs by the action of the abdominal muscles.

The immediate causes, or the physiological pathology

1. DEFINITION.—The rejection of the contents of

* The mechanism of vomiting has been a subject of discussion with both physiologists and pathologists. Three principal opinions have been entertained on this subject. The first and most usual opinion is that the stomach is passive in the act, and that the contraction of the diaphragm and abdominal muscles on that organ is the sole cause of the phenomenon. "This view was adopted by RICHARD, HISTORIS, and FREDERICUS; while MARQUIS, MAIGAUDTE, PORTIOL, TANTUM, GRAVES, SPORES, and HALL have embraced more or less contrary opinions." MAIGAUDTE attributed vomiting exclusively to a gradual anti-peristaltic movement and contraction of the stomach. PORTIOL concluded that this act takes place during expiration, consequently during relaxation of the diaphragm. That vomiting may take place without the action of the diaphragm, is shown by a case observed by Dr. STREPHUS. It was a case, where vomiting was a principal symptom, but the stomach was found situated above the diaphragm. In a case recorded by M. LEPINE (Journal de l'Academie, 1844), in which abdominal parietes having been accidentally laid open in the course of observation, the only contraction which was perceived at the stomach was the peristaltic action of the esophagus; the splinter is essential to the act of vomiting, for its fibre can resist by its contraction, the combined forces of the muscles of the diaphragm. The restricted or frictions efforts at vomiting are owing to the contractions of the cardiac splenic nerves, or as observed, and projects at expulsion of the contents of the natural cavities, is performed by the muscles of expiration, and whilst the diaphragm is relaxed and laid open upon the lungs by the action of the abdominal muscles.

CLASSI.—PATHOLOGY—SYMPTOMATOLOGY AND THERAPEUTICS.* (See Preface.)
VOMITING AND RETCHING

As Therapeutical Means.

generally much benefited by a suitable emetic and free vomiting. Croup, whooping-cough, asthma, septic seizures, spasm of the larynx, and laryngitis, convulsion of the lungs, bronchiitis, and bronchial catarrh, are severely relieved by emetics. In most of these, ipecacuanha, in a full dose, is the best emetic; but when there is fever or inflammatory action, the vomiting must not be induced by this means, but if it fail of producing vomiting in a short time, a full dose of ipecacuanha should be given. The sulphate of zinc and ipecacuanha, conjoined with castor oil or other warm spices, are most useful when vomiting is indicated during states of vital depression or exhaustion; and in cases of poisoning by sedatives, narcotics, &c.

5. a. The invasion of fevers, continued or exacerbating, is often most satisfactorily treated by an active emetic; and, as well as in affections of the respiratory passages and organs, the good effect is enhanced by the free promotion of vomiting, and by exhibiting with it, especially in the warmer climates, the warm infusion of camomile flowers, or decoctions. — Ashes and other periodic fevers, especially remittent, intermittent, and bilious fevers, are also much benefited by initiating the treatment by an active emetic, and by promoting its effects by these means. Antiperiodic and febrifuge remedies, and cholagogue purges exert a more certain effect when they are preceded by free vomiting, artificially produced.

6. c. Various disorders of the digestive canal are mostly beneficially treated by procuring free vomiting at the commencement of the disorder or of the treatment. The several forms of Cynanche or Angina, especially when they embarrass respiration or deglutition, often require a recourse to emetics. In the more malignant states of Cynanche, or those characterising Scarlet fever, the sulphate of zinc, or ipecacuanha, conjoined with castor oil or other spices, and promoted by the decoction of senega, and by tonics, stimulants, camphor, ammonia, &c. should be preferred to others.

t. d. Some forms of indigestion, or those arising from accumulations of morbid sordes, or cedrites, and torpid states of the biliary formations, are relieved by ipecacuanha, and, by morbific appearances of the evacuations, are often the most successfully treated by commencing with an ipecacuanha emetic. All forms of dysentery, inflammatory or scrophulous, syphilitic, or asthenic, acute or chronic, endemic or epidemic, simple or complicated, hepatic or scarburitic, derive benefit from free and copious vomiting, especially when produced and promoted by means suited to the peculiarities of individual cases. Ipecacuanha is, however, the emetic which is most generally applicable to dysenteric affections; and next to it the sulphate of zinc. After a free effect has been procured by means of ipecacuanha, this medicine, — so valuable in dysenteries and chronic diarrhoeas, may be continued subsequently, in as large doses as the stomach may tolerate, but preferably in the form of pill, combined with appropriate remedies — narcotics, aromatics, tonics, &c.

5. a. Hypochlorhydria and Melancholia are sometimes relieved for a time by an energetic emetic, judiciously selected and exhibited. But it ought, in order to be of service, to be followed by medi-
cines calculated to promote the secretions and ex-
creations, and to impart tone and energy to the organic nervous system and to the organs which it actuates, by exercise, change of air and locality, and by travelling and occupations which both employ and interest the mind.

9. 2. Vomiting and Retching as prominent Affections, or States of Symptoms of Disease. — Retching on the bowels, especially in a state of violent severe constitutional disease, is the all-important phenomenon; it is a remarkable and distressing symptom, owing — 1st, To infectious or poisonous ingesta. — 2d, To severe constitutional disease, as at the invasion, or in the course, of severe exanthematic or continued fevers, or of pestilential malaria; — 3d, To severe functional disorder or irritation, or structural disease of the stomach itself; — and 4th, To sympathetic disease or irritation in some allied or more or less distant organ. The presence of either vomiting or retching, or of both, necessarily induces the physician to inquire — 1st, As to the exciting cause, manifest or presumed; and 2dly, As to the pathological states to which either or both may be referred.

10. a. When a physician is called to a person who has previously enjoyed good health, or who has not complained in such a manner as to indicate a liability to an attack of vomiting or retching, then he should suspect the nature of the ingesta as having produced it, and inquire as to the food or drink, or other matters which the patient may have taken; and the matters ejected from the stomach should all be preserved for future examination, if circumstances should arise to require such examination. Where neither food nor drink is the cause, then poisonous matters taken voluntarily or accidentally, or given by others, ought to be suspected, and be carefully and artfully ascertained, and the matters rejected from the stomach carefully preserved and examined by a competent person. If poisonous substances have been taken or given, or are manifestly by the character of the vomiting, by the allied symptoms, or by the state of the vomited matters, or by their presence in these matters, the antidotes and other means of treatment described with reference to the individual poisons (see that article) will be required.

11. a. When the vomittings or retchings are not caused by the ingesta, their pathological relations must then receive the necessary attention. In infants and children, as well as in adults, these affections may proceed from hot seasons, owing to bilious or gastric disorder; from a bilious or gastric, continued, or remittent fever; from the invasion of exanthematic fevers, especially scarlet fever and small-pox; and, in the former class of patients, more frequently than in the latter; from disease of the brain or of its membranes. They may be the invasion of the usual forms of cholera, or of gastro-bilious disorder, during summer and autumn, or the very tender and urgent symptoms of pestilential cholera; or, in warm climates, of haemagastrosis or yellow fever. In these climates, also, they may usher in remittent or other fevers and maladies; and in all these, although most severe and even dangerous, as well as the most prominent, manifestations of disease, they are very far from being the disease itself, or even the greatest part of it.

12. c. Severe functional disorder, local or constitutional, will occasion vomittings or retchings, as that following dissipation or
VOMITING AND RETCHING — FROM ORGANIC LESIONS

§ 5., and that occurring at the commencement of the fevers, and pestilential maladies already noticed; but the most distressing attacks of retching and vomiting are often caused by the motions of vessels at sea, and by organic lesions of the stomach itself. Of the former, a more particular notice will be taken in the sequel under the head of Sea-Sickness, or vomiting and retching during voyaging by sea; and as to the latter causes, viz. inflammation and structural changes of the Stomach (§ 22—95.), the symptoms now being considered, when arising from these lesions, are duly noticed at that place. To what I have there stated, and to the article on the pathology of the Digestive Canal (§ 37—43.), I must refer the reader. But there are other remarks which may be added at this place calculated farther to elucidate the history of vomiting.

13. i. VOMITING AND RETCHING FROM ORGANIC LESIONS seated in, or impinging, the stomach. — These lesions have been described at the places now referred to; and, amongst these, ulcerative perforation of the stomach, either commencing in this viscous, or extending to it from structural changes in adjoining parts, has occupied a conspicuous rank. Ulcerous lesions may give rise, even to previous agglutination or adhesion of the opposite serous surfaces, to communications—

1st. Between the stomach and the substance and vessels and ducts of the liver, owing most frequently to abscess in the latter viscus;—2d. Between the stomach and the pleural cavities and lungs;—3d. Between the stomach and pericardium;—4th. Between the stomach and vena cava;—5th. Between this organ and portal vein;—6th. Between the stomach and external surfaces of the abdomen;—7th. Between this viscous and the gall-bladder;—8th. Between the stomach, gall-bladder, and duodenum;—9th. Between the stomach and duodenum;—10th. Between the stomach and some part of the small intestines;—11th. Between the stomach and colon;—12th. Between the stomach and peritoneal cavity. Other fistulous communications between parts of the digestive canal and other viscera are not so rare in practice, and are occasionally attended by vomiting; but they are noticed in their appropriate places. Of the several kinds of perforated communications between the stomach and other visceras now enumerated, the first is most commonly the result of abscess in the liver; although it may arise otherwise in rare instances, as in a case which came under my care where the perforation of the stomach extended far into the substance of the liver. The second is also most frequently the result of an abscess opening into the stomach. The third, fourth, fifth, and sixth, almost in all cases, are referable to perforating ulceration, cancerous or simple, commencing in the stomach. The seventh and eighth forms of fistulous communication are most commonly caused by large gall-stones in the gall-bladder. The ninth, tenth, and eleventh most frequently proceed from cancerous or simple ulceration commencing in the stomach or in contiguous parts of the upper alimentary canal.

15. This greater rarity of gastro-cole fistulae, as a sequel of simple ulcer, may, according to Dr. Murcison, "depend on three causes: viz., the fact, that simple ulcer is much more rarely met with in that part of the stomach nearest the colon—the great curvature (in the only..."
VOMITING AND RETCHING — FROM SYMPATHETIC IRRITATION. 1369

of 220 cases); and that there is a greater tendency in cancer to contract adhesion to neighbouring parts before perforation; while, at the same time, the cementing matter is of a less permanent quality than the lymph thrown out in the vicinity of a simple ulcer. The absolute frequency of gastro-colic fistula, as a sequel of cancer of the stomach, can only be approximated. Dr. T. observed this lesion in 6 out of 160 cases, or 3.75 per cent.; Dr. B. in 11 out of 507 cases collected by him, or 2.17 per cent.

That the ulceration generally commences in the stomach, I have shown in the places above referred to, but I have admitted that it may originate in the colon or other parts, and extend by perforation into the stomach. The cases recorded by Dr. Muncaster fully illustrate this inference. He remarks that, "Out of the thirty-three cases, there is every reason to believe that the disease commenced in the stomach in twenty-six; in four cases there are no points of departure for the symptoms in the opinion of the point; and in three only does the disease appear to have been most advanced in the colon after death." In cases where tubercular disease or abscess finds its way into the stomach or into both stomach and colon, as in very rare instances, when these diseases are so far advanced that the disease of the kidney or the gall-bladder, the cause of the alteration is manifest.

16. III. The Diagnosis of gastro-intestinal, or gastro-colic fistula, depends chiefly on the characters of the matters thrown off the stomach. This topic is partly discussed, especially as respects the antecedent and many of the existing symptoms, in the articles referred to above; but those phenomena which indicate the presence of this fistula have not been so fully described. Vomiting is always present, although it sometimes recurs only at intervals. It is often preceded, and attended, by fecal eructations, or by bilious, dark, or gummosus matters in the ejected fluids. When there is a free communication between the stomach and intestine, the vomited matters generally are more or less fecal. But where the fistula is long or circuitous, vomiting of fecal matters may not, or only occasionally, be observed. Dr. Muncaster remarks that in the year 1840 there were fifteen cases in which the history was clear, fecal vomiting was observed in eleven, and fecal — perhaps fecal — in three; and he draws the following conclusions: — "1. Fecal vomiting is probably present in all cases in which the opening (except this be very minute) is situated in the fundus, or great curvature, of the stomach, and may also be present when the disease is in the pylorus. 2. In all cases in which food is vomited the opening is at or near the pylorus, so as to preclude the passage of food." In cases of cancer of the pylorus or duodenum, vomiting may be less after the formation of the fistula than before, as the food in the former case may pass into the intestine, into which the fistula opens.

17. Where gastro-intestinal or colic fistula exists there may be present eructations with a fecal odour, as well as fecal vomitings; or there may be only fecal eructations. Next to fecal vomitings, the presence of indigestible food in the stools is an important indication of gastro-intestinal fistula. I have long supposed that at least some of the cases of intempery, amongst the many which came before me at the Infirmary for Children, were actually instances of this form of fistula. As the disease advances, as it usually does, to a fatal issue in the course of several days, (although it is sometimes prolonged to some weeks or even months, with intervals of partial case,) diarrhea with indigested matters in the stools soon after they had been taken, or an occasional recurrence of constiveness, emaciation, anemia, general cachexia, or yellowness of the body, as described in the articles already referred to, are commonly observed.

18. III. Vomiting and Retching from Sympathetic Irritation. Irritability of the stomach, so great as to be attended by vomiting or retching, on receiving all, or most kinds of food or drink into the stomach, is often occasioned by vascular erythremia, inflammation, or organic alterations of an adjoining or even of a distant organ or part. The vascular excitement of, and determination of blood to the uterus during pregnancy, and the degeneracy of the various tissues during the advanced months of gestation, are often productive of vomitings or retchings; and organic and inflammatory diseases of the uterine organs, frequently occasion the same symptoms, especially in delicate and susceptible females, or when these diseases are of an acute or severe kind. As may be readily inferred, inflammations and organic lesions of any of the allied or adjoining viscera are very often are productive of vomiting, the rejected matters consisting, as in the preceding diseases, chiefly of the ingesta, and of watery,ropy, and mucous fluids, sometimes coloured with bile, unless when congestion, inflammation or abscess, may give rise to the discharge of blood or purulent matter from the stomach, or from adjoining parts, communicating with the stomach. Enlargements, morbid growths, or other lesions, in the liver, spleen, pancreas, mesentery, omentum; disease of the diaphragm, or of the gall-bladder and ducts; misplaced or suppressed or retrocedent gout; suppression of urine, or retention of this excretion, verminous diseases, &c., severely occasion vomitings when they reach an advanced stage of development.
VOMITING AND RETCHING — FROM SEA-SICKNESS.

various mechanical or structural causes of intestinal obstruction, as shown in various places (see Arts. Colic and ileus, Concretions, Biliary and Intestinal, etc.); more particularly when the terms are used to denote a consistence, in character, and when the vomited matters present a foetid or faecal odour, or a more unmistakable faecal character. In all cases of obstruction, and irritation, of any of the duets and canals within the abdomen, especially when the obstruction is caused mechanically or by a solid body, the sympathetic occurrence of vomiting is generally very urgent and distressing, although often presenting intervals of comparative ease. In all cases of vomiting and retching, the history of the case should be ascertained as fully as possible.

20. Besides these more strictly local diseases, which are attended by vomitings and retchings, there are several constitutional maladies, especially those adverted to above (§§ 18, 19.), in which these symptoms are of a most prominent character, and proceed from contamination of the blood, acting both on the frame generally and upon the stomach and its allied viscera in particular. No doubt the grand object of all these illnesses be the humasplastic pustulence, or the contamination occasioning malignant purpuric fevers, or that arising from poisoned wounds, inoculation, &c., the meridip impression is primarily and energetically made upon the organic nervous system, the retching and vomiting often following closely upon it; but nevertheless, this impression being made, the alteration produced in the blood aids it, and promotes both by increasing the depression of the organic nervous force, and by irritating the stomach and adjoining parts, thereby rendering the vomitings of a more serious, dangerous, or obstinate character, as evidenced in these maladies.

21. IV. VOMITING AND RETCHING FROM SEA-SICKNESS are common to all persons soon after they feel the motions of vessels on the sea, if they have not acquired an immunity from this suffering by habit.

22. I. DESCRIPTION.—In some, vomiting is present as a principal symptom, being prostration, faintness, vertigo, and apathy. In others, vomiting takes place more or less quickly, after nausea is first felt; and in many the nausea and distressing retchings, with headache, vertigo, and prostration, continue or return at shorter or longer intervals after the stomach has been completely evacuated, but only if the motion of the vessel continues. When the retchings continue or return after free vomiting, a coppery fluid, mixed with more or less bile, is evacuated, owing to the emulgent operation of the retchings on the liver, gall-bladder, and ducts, thereby producing a favourable influence on certain diseases noticed hereafter (§ 25.).

23. The severity and duration of sea-sickness depend much upon the susceptibility of the individual; and the extent of motion to which he is subjected; and, although generally all persons are liable to sea-sickness on first going to sea, yet its severity and continuance are great in proportion to weakness and delicacy of constitution. Usually, however, the sickness either subides or ceases altogether in a few days; and in previously healthy persons it is followed by a good or craving appetite, and a return of health, although the cause of the suffering may continue. Many persons who, from frequent or prolonged voyaging, have become exempt from sea-sickness, at least whilst at sea, experience a recurrence of it when they return to sea, after having passed a considerable time from the sea; and again, in short duration, or slight in these persons. Sea-sickness occurring during a short passage, as in crossing the Channel, immediately ceases with the stillness of the vessel, or on landing, vertigo only remaining for a time. Some delicate persons, who are very susceptible of sea-sickness, are also liable to nausea and retching from the motion of a carriage, especially while they remain inside, but escape from the sickness when they ride outside.

24. II. PROGNOSIS.—Sea-sickness, although mentally and physically most depressing, and although both vomitings and retchings are most severe, is generally untended by danger, and it very rarely terminates fatally. When this event takes place, it is more the consequence of the continued nausea, and of the loathing of all kinds of ingesta, owing to their inducing retchings, and of the resulting inanition, exhaustion and fatal sickness, than of any alteration of structure, or continued lesion, upon the cholic and vomiting parts of the body.

25. III. THE NATURE OF SEA-SICKNESS has been a subject of frequent discussion. The brain, the heart, and the cerebrospinal nervous system generally, have been severally referred to as the seat of this distressing disorder. That these are more or less affected during its continuance — that the brain and nervous system are impaired in volition and in the vigorous discharge of all their functions, the mental and physical, and that the heart acts feebly, although sometimes rapidly, but without tone or vigour, is equally manifest, until the retchings and vomitings occasion more or less reaction, accompanied with perspiration, which varies with the severity of the sickness, and the constitution of the patient. But the affection of these — of the cerebrospinal nervous system and of the vascular and muscular systems, with the organs and parts more immediately concerned in the act of retching — is the necessary result of the effect produced by the motion of the vessel upon the semilunar and allied ganglia, and the viscera they endow with the organic nervous force. This effect continues until retching and vomiting supervene and occasion more or less reaction according to the constitutional powers of the sufferer. That the primary influence of the vessel's motion on the semilunar and allied ganglia is depressing may be inferred from the disturbance referred to the epigastric region, and from the general physical and mental prostration preceding the retchings. That vomiting and retching, each varying in grade and character, follow very powerful depressing influences, is shown by the effects of most excitatory and exhausting agents.
VOMITING AND RETCHING — FROM EXHAUSTION, FERMENTATION, ETC. 1371

whether poisonous, morbid, or infections — which act more especially or immediately on organs or surfaces endowed by the organic nervous force. It may therefore be inferred, that the vital depression produced by the vessel's motion is the chief cause of the sickness and vomiting, the irritation caused by matters contained in the stomach being merely aiding in developing the retching and vomiting, this act and the evacuation of the stomach affording a slight temporary relief, the depression and sickness still continuing more or less, or for a period, according to the continuance of the cause, and to the constitution and predisposition of the sufferer.

26. THE REMEDIAL INFLUENCE OF SEA-SICKNESS is sometimes remarkable in several diseases, more especially when the sickness is attended by free vomiting, the appetite returning afterwards, and when the patient does not suffer incontinently, or when the suffering is not long continued. In severe hooping cough, especially in persons near or past puberty, and in general famines, sea sickness is often of marked advantage. In this complaint, the patient, sufficiently protected from exposure or weather, may be placed in a rowing or sailing boat, where much of the sea is observed, and carried out to sea, until vomiting takes place, when a return to land may be directed. In other cases and circumstances, a short voyage in sailing vessels furnishing the requisite accommodations, may be taken with benefit. A similar advantage may accrue in cases of tubercular consumption, as I have shown in that article (§ 420.); in hemoptysis; in spasmodic asthma; in chronic bronchitis; probably in some cases of chronic diarrhoea and dysentery, when suitable accommodations are afforded, and in torpid states of the liver, &c. In these cases, the influence of nausea in lowering vascular action and removing spasm, and the action of retching and vomiting in emulaging the billary apparatus (§ 21.), and in evacuating mucous accumulations in the bronchi, are of essential service. By this action also congregations of the lungs and liver are removed, or are aided in their removal, and a healthy secretion of bile promoted — circumstancies of great importance in several pulmonary, bilary, hyperchondriacal, gastric and intestinal diseases.

27. THE RETCHINGS AND VOMITINGS which may be viewed as idiopathic or primary, and which are not necessarily connected with inflammation or structural disease of the stomach and allied viscera, although they ultimately, by persistence in their cause, become thus associated, are those which take place in the morning, and which either recur frequently or habitually, and in which the patient generally removes for the time with a glass of brandy, or of brandy and water, or of some other favourite liquor. In these cases, morning sickness is the result of exhaustion (from previous over-stimulation, and for a time is merely functional, but sooner or later it becomes more and more structural. The same form of sickness often follows in the morning heavy suppers, either with or without excessive drinking. At times there is a celestial explanation of sickness or vomiting habitually or frequently in the morning, and more especially if he have recourse to spirits to remove it, before any food can be taken, is most positive evidence of such person being an incurable drunkard, although he may never have been intoxicated.* The form of disorder may be considered as allied to vomiting from sea-sickness (§§ 21. et seq.), the most idiopathic form of vomiting.

28. When the functions of the stomach are exhausted by the excessive excitations of intoxication, or by the irritating influence of wholesome food, and more especially by the ingestion of substances which readily enter into the acetous, the lactic, or the vinous fermentations, when received in the weak and exhausted stomach, then pain, vomiting or eructations are produced by the gaseous products, by the acidity, and by the various irritations which result from the fermenting substances, which, if they fail in undergoing these processes during the imperfect digestion, experience putrefactive changes, and occasion the same, or even more serious and more obstinate disease.

29. When the digestive processes are impaired or exhausted, owing to debility (see that article, § 15. et seq.), or to inordinate muscular or mental exertions, or to local or constitutional disease, the articles of food most prone to undergo fermentation, as bulky vegetables, raw fruits, fermented bread and liquors, &c., produce an increase of disorder, by the fermentation which ensues, and the frequent repetition of such disorder at last passes into more serious disease, which is characterised by recurrences of retching and vomiting, and by gastrodynia, whenever such

* The following cases will illustrate this. A young man in a large wine merchant's house, and having free access to extensive wine vaults, was helped, after habitual sickness and vomiting in the morning, with most violent pain in all the smaller joints, and especially in the wrists and ankles. He came under my care, when he complained that sickness and vomiting every morning upon getting out of bed had continued for three or four years; that it was instantly cured by a glass of brandy, but that he could take little or no breakfast. As soon as he returned to business in the morning, he continued drinking at intervals sherry or port wine or brandy, as either came in his way, and he thus took from two to three bottles of wine, besides brandy every day, unless brandy was too strong when his supply was not so liberal. He recovered his health, relinquished this habit; and he has for very many years been sober and temperate. He never had any symptom of disease of the stomach or liver, and he is the only instance I can recollect of a complete reformation from dram Medalness.

A cook in my family was always sick and retching in the morning, and could take no breakfast. Her principal meal was supper; soon after which she retired into her own room, and nothing was known of her until she had partly recovered from her sickness and resumed her morning duties. Upon hearing this I became alarmed at the probable consequences of her after-supper indulgence, and means were devised to prevent her apartment from being fastened on the inside, and then she was there found drunk. These cases are not of infrequent occurrence; but in some instances vomiting is only occasionally present, chiefly in the morning; a chronic diarrhea, sometimes passing to a fatal perityery, with diseased liver, taking its place. Several cases of very young persons, mostly females, who have died from the excessive use of spirituous liquors have been brought under my notice. These were characterised by habitual sickness and retchings in the morning, which were allayed by the acuteness of the stimulus or by strong tea, but followed, after a longer or shorter period, by enlarged and fatty liver; or by emaciation, chronic diarrhoea or dysentery, with ulcerated bowels; or by the most violent pains in the extremities, of a mixed neuritic and gouty or rheumatic character, terminating in several of the cases before the age of twenty. In one case, at the age of seven, the growth was remarkably stunted owing to this vice, all the others who had contracted it at an earlier age were very much under size. In this instance the fatty liver filled almost the whole abdomen, and descended deep into the pelvis, and produced an abdominal enlargement as great at the full period of pregnancy.
VOMITING AND RETCHING — FROM SCARINA. — TREATMENT OF.

Disease is aggravated by the ingestion, or commixture of fermentative substances. The connection of fermentation in the stomach with indigestion and vomiting, has been well discussed by Dr. Turnbull, and although the doctrine of fermentation has been pushed too far by him, there can be no doubt of the importance of giving due consideration to changes of this nature, which certainly take place in the digestive canal, when the nature, the quantity, and the admixture of indigestible, saccharine, and putrescent substances are taken into the stomach during functional or structural lesions of the digestive organs. Persons addicted to the excessive use of intoxicating liquors, experience more or less fermentation in the stomach after the excitement caused by these liquors has subsided; and the products of the fermentation, acting on the exhausted organ, frequently produce that amount of irritation, which is manifested by nausea, retching, vomitings and gastrodynia, and which the drunkard relinquishes by a recourse to the accustomed stimulus.

30. VI. VOMITING ATTENDED BY THE DISCHARGE OF THE SCARINA VENTRICULI. — In 1842 Professor Goodwin described this remarkable production, and some singular cases of this kind have occurred, most of which have been either observed or referred to by Dr. Turnbull, of Liverpool. I have not observed more than three instances of this production in the substances vomited since attention was first directed to it, and these occurred in cases of organic disease of the stomach, in which the fermentative and putrefactive processes appeared to have been readily produced. The writer just mentioned has noticed thirty cases of scarina ventriculi recorded by various authors, and has himself observed six. Of these eighteen had terminated fatally. He arranges these cases in four groups: —

1. Cases in which ulcers or cicatrices arising from them, or some other non-malignant disease of the stomach, obstructed the pyloric orifice. — 2. Cases of cancerous disease contracting the pylorus. — 3. Cases in which there was no disease of the stomach, but displacement of some other condition obstructing the pylorus. — 4. Cases in which the disorder may have been functional, recovery having taken place more or less perfectly." The analysis of these cases furnishes the following: — the disease is more common in males than in females, in the proportion of twenty-four to ten, and between the ages of thirty and fifty. Of the three cases which I saw two occurred in confirmed drunkards between forty and fifty-five years of age. In all the cases, vomiting was the prominent symptom; flatulent distention, offensive excretions, pain in the stomach, costiveness, emaciation, and anaemia being also present. According to Dr. Turnbull, the sensation of "something alive in the stomach," was also experienced, but this was not remarked in any of the cases for which I was consulted. Dr. B. Jones found the urine alkaline, and this excretion has, in some instances, continued to the last. The weight of the symptoms, the symptoms in the nature of blood, and the symptoms in the nature of disease, especially when the blood is contaminated and vital depression is extreme, I have seen the effects in numerous instances, since 1817, when I first employed these substances in the hemagastriatic pestilence or yellow fever. In all these diseases the usual means of allaying vomiting were useless, and the vital depression, the sense of sinking and mental apathy, and therewith the vomiting; which symptoms generally terminated in a fatal pumping up, or rejection of the contents of the stomach, without retching, but often with singultus, when sedatives and narcotics were employed.

31. VII. TREATMENT. — I. TREATMENT OF SYMPTOMATIC VOMITING AND RETCHING. — It is manifest that the treatment of retching and vomiting can only be successfully accomplished by a strict examination of the history of each case, and of its causes, extrinsic and intrinsic; and by ascertaining the particular category of causes to which each individual case should be referred — whether the vomiting has been occasioned — 1st, By the ingestion of an injurious or poisonous substance (see Poisons); — 2nd, Or by the invasion or accession of a febrile, exanthematous or pestilential malady; — 3rd, Or by disease of the stomach or bowels, or of some adjoining organ or part; — 4th, Or by sympathy with the irritation or structural lesion of a more remote organ; — 5th, Or lastly, by the abuse of intoxicating or stimulating liquors.

32. A. If the vomiting be caused by poison, ingesta, it is obvious that the means advised is such cases in the article now referred to are required, conformably with the evidence obtained as to the nature of the poisonous substance which has been taken. To this extensive subject I can add nothing to what I have adduced in the article Poisons.

33. B. If there appear any reason to ascribe the vomiting to the invasion of an exanthematous, infectious or pestilential malady, especially when any such is prevalent or epidemic in the same locality, or when the vomiting is associated with eluviation or any other symptoms of the invasion of any of these maladies, then the treatment advised for the accession of such malady ought to be adopted. (See the treatment recommended on the accession of the Choleric, and Hemagastriatic Pestilences of Scarlet Fever, Small-pox, &c.)
VOMITING AND RETCHING — TREATMENT OF.

38. ii. TREATMENT OF SEA-SICKNESS. — This is a very hopeless subject, yet it is nevertheless one which should not be abandoned, for with care and judgment sea-sickness may be more or less alleviated and its duration abridged. The usual means employed for it are seldom of service and often tend to produce the nausea, without ultimately preventing the vomiting. It is generally preferable, when the sufferer is young or even moderately strong, to partake of such food and drink as he may prefer, thereby to prevent ineffective retchings; and when free vomiting is accomplished, to take small and frequent doses of a suitable anodyne, in small quantities of fluid. Substances of large bulk, or even in moderate quantity, or gaseous fluids, by distending or filling the stomach, generally bring back the retching and vomiting. During the nausea, or even after it is moderated, the stomach is quite incapable of digesting alimentary substances; therefore their presence in the stomach acts only as an irritant of the weak and susceptible organ, and in a short time brings back the sickness and vomiting. Having, therefore, promoted a free evacuation of the stomach, in the way now advised, small doses, often repeated, of either hydrochloric acid, or tincture of opium, or chlorodyne, or of chloroform, or of hydrochloric ether, may be given in small quantities of a demulcent mixture, which may be made agreeable by the addition of a few drops of an aromatic cordial. Creosote has been recommended, but its colour is disagreeable to many persons; but, when prescribed for sea-sickness either in the form of pill, or in a demulcent mixture, it should be given in small doses, or not exceeding half a minim for a dose, which may be repeated according to its operation. The demulcent and anodyne medicines may be given in any of the mint waters, especially when the patient is disturbed by flatulence and eructations, and any cordial or aromatic may be added if sinking at the epigastrium or vital depression be experienced.

39. Females and delicate persons, subject to sea-sickness, should retire to their cabins immediately on embarking, if the voyage be likely to be longer than a few hours, or to continue during the night. Unless the sufferer be weak, or extremely depressed by the sickness, retchings and vomitings, it is generally preferable for him to keep up and struggle against his enemy, as he will be the more likely to overcome ultimately, and to shorten the duration of the attack. If he have any return of appetite after vomiting, it should be indulged in great moderation, the food being the most digestible within his reach; if sickness and vomiting recur, they will generally be of short duration, and be followed by a return of appetite, which, if properly indulged, will be generally followed by health. This plan is to be preferred if a long voyage, or one beyond three or four days be anticipated; for, by that time, or not much longer, the evil will cure itself. It is only for the more severe cases, or in short voyages, or for delicate females and weak persons, that the medical advice given above (§§ 38), is either much required, or particularly appropriate.

40. iii. TREATMENT OF RETCHINGS AND VOMITINGS CAUSED BY DRUNKENNESS AND BY FERMENTING INGESTA. — The drunkard generally knows well how to remove the morning effects.
of his previous indulgence, and he finds the recurrence to his accustomed liquor, or to one still more energetic, to be the most efficacious remedy. But lie counts not the ultimate cost, vice not the ruin of the liquor indulged in, organic disease of the stomach, pyorrhea, liver, &c.; or chronic diarrhoea, or dysentery, delirium tremens, &c., often complicated with the foregoing. Sofer remedies for retching and vomitings consequent upon Drunkenness are the airied waters, the compound decoction of aloes with cinnamon water, creosote in pills or in mucilaginous mixtures, and the means advised in the article now mentioned (§§ 15. et seq.). When the vomitings are of daily recurrence, it is evident that the only permanent cure is to subject the patient to such restraint as may be legally permitted, seeing that he is incapable of restraining himself. This is, however, one of those forms of moral degradation, against which the laws have no provision, and for which medical aid is rarely of any avail, especially as regards prevention or permanent cure—

"Heemap hominibus, non eum Ditis agitur."

41. Vomitings caused by excessive fermentation in wine and spirits, are generally allayed by medicines, which either arrest or neutralise the process, or develop the vital force of the organ, or allay excessive irritability of it, or operate in more than one of these modes. The sulphate of soda, the alkaline carbonates, the carbonates of magnesia or of lime, calcined magnesia, the citrate of magnesia, the subnitrate of bismuth, the bicarbonate of soda, are severally of use in these cases, especially when prescribed in conjunction with tonics, stimulants, and anodynes, and sometimes with narcotics. As the fermentation and the vomitings are generally attended by impaired organic nervous force, as well as by irritation of the digestive mucous surface, tonics and stimulants are required for the former morbid condition, whilst anodynes, especially hydrocyanic acid, or small doses of opium, or of opiate preparations, or of the lupulus, or of hyoscymus, are appropriate for the latter. In many instances, in addition to a specific, recourse is made to certain of the above, in varying combinations, other substances which are calculated to remove irritation and to check fermentation, and at the same time to promote a healthy secretion from the stomach, liver, and duodenum, may be given from time to time. Of these the most beneficial are Hydrocyanum cum crebri, the pilula hydrargyri, and calomel, and these, according to circumstances, may be given in full doses with opium, creosote, the preparations of hop, &c. Small doses of the nitrate of potash, or of the hydrochlorate of ammonia, given with hydrochloric ether, in mint water, &c., are also beneficial in these cases.

42. In all cases of retching and vomiting, referable either to the abuse of intoxicating liquors, or to extreme dyspepsia attended by vomitings, or to gastric fermentation, or to pregnancy, attention should not be directed alone to the morbid condition of the stomach, for the vomitings or retchings will not be permanently removed, or they will be liable to recur after a time, if the biliary and gastro-intestinal secretions and excretions be not duly promoted. In all such cases, therefore, having palliated the vomitings, a moderate action should be kept up on the bilo-intestinal functions; and the means which I have most frequently employed have been the hydrargyrum estræa, or blue pill, or Plummer's pill with soap taken at bedtime, once or twice in the week, and the following draught early on alternate mornings, or every morning, or at bedtime;—

No. 379. B. Potassii Bl.-carb. gr. xii. ad xvii. — Ammonii Carbonas. gr. viij. — Timi. Sentic. Comp. i. — Timi. Cardamomi. Comp. ii. — Infus. Semen Comp. iii. — Infus. Gentianæ Comp. ad lit. Min. cit. Houstons. To this draught may be added, according to the peculiarities of the case, a dose either of hydrocyanic acid, or of the extract of tartar emetic.

43. Vomitings attended by the Reaction of the Sarcina Ventriculi, are generally the result of protracted indigestion, attended either with fermentation, or with organic disease, malignant or otherwise, of the stomach or pylorus (§§ 80. et seq.). In the majority of these cases the means already advised may first be employed, and if these fail, as they often will in this form of complaint, other more energetic medicines should be prescribed, generally in efficient combinations, viz. camphor, creosote, and small doses of opium, made into pills, with any suitable powder, and with either common tar (pia liquida), or the balsam of Peru. Having been taken for a time, the exhibition of tonics with alkalies, or alkaline carbonates and hydrocyanic acid; or of the sulphates, or the pyroxilic spirit, or linewatter, or the chlorides, may be tried, conjunct with preparations of either cinchona or cascarilla bark, or with an infusion or decoction of cedar or pomegranate bark.

44. V. Diet in Cases Liable to Vomiting, &c.—Vomitings, when palliated or removed, present the greatest difficulties as to the selection of alimentary substances. As a general rule, all such as are liable to readily undergo any of the fermentative processes should be avoided. Most alimentary substances undergo one or other of these processes, whether of an acid, or of a putractive, or of a socharinic nature, when mixed with the morbid secretion of the stomach, and when the organic nervous force of this organ is much impaired. Still there are aliments which are much less prone to undergo these changes than others, although much depends upon the peculiar inscrutability of the patient. Frequently the food which the patient most desires in these cases, or for which he feels a relish, will be found the most easily digested or retained. Substances which readily undergo fermentation, as fermented new bread, vegetables, raw fruit, the ingestion of varieties of food, and fermenting liquors should be avoided. In this subject, however, I can add nothing to what I have advanced in the article on Indigestion. (See §§ 55. et seq.)

WORMS. — INTRODUCTION.

2. The above definition is a modification of that given by Dr. Kikkenmeister, in the very able work On Animal and Vegetable Parasites, by Dr. Lankester. Leuckart (Parasites et Parasitisme, in Verhand. Arch. 1852) remarks, that whenever a species is too small and too imperfectly armed to overcome and destroy another living being upon which it instinctly directs itself to seek for nourishment, it must be contented with robbing it, by feasting upon its blood, juices, and solid parts. As respects the human body especially, it would be more correct to state, that, whenever the vital force of this body is reduced by disease, insanity, and exhaustion, it is then exposed to the invasion of those parasites which are peculiar to it; and that these parasites are developed and multiplied with a rapidity generally in proportion to the diminution of vital force or of vital resistance to their multiplication and multiplication. The only animal parasites which appear to originate upon the human body, belong to the classes of insects and worms, and probably also to the infusoria. As far as we know, these parasites of men are not subject to the attacks of secondary parasites. Many of them profess to be man and other mammals, whilst others are peculiar to him.

3. It has been very justly remarked by Dr. Lankester, in his excellent and instructive preface to the work just referred to, that the study of animal parasites involves questions of the highest scientific and practical interest, and that it teaches that, though scientific theories may sometimes be barren of immediate practical results, they cannot fail to free the mind from prejudices which lead to erroneous practice, and even to disastrous results. On this ground, therefore, he refers to some apparent of the least practical topics, with the hope of assisting the reader to understand those generalisations which the subject of animal parasites involves. But however barren the consideration of the generation and reproduction of organic beings may at first sight appear to be, it is of the utmost importance in respect of its ultimate or practical results; and Dr. Lankester has done medical men a great service in furnishing them with a compendium of the results of the recent researches of Dr. Kikkenmeister and others as to this subject, especially as regards the history of the human intestine. Dr. Lankester justly remarks, that, although it was easy to account for the existence of intestinal worms, by referring to the ingestion of their eggs, yet a difficulty presented itself regarding hydatids, which evidently had an independent animal existence. Hydatids exhibited no sexes, they produced no eggs, and readily supported the theory of "spontaneous, or equivocal generation." Even as this theory was driven successively from every other part of the animal and vegetable kingdoms, it "found a refuge amongst the strange and paradoxical creatures imbedded in the tissues of men and other animals, far removed from any external influences." The time has, however, at length arrived, when it can be demonstrated, that the hydatid worm is no longer to be regarded as the result of a "spontaneous" or "equivocal course of atoms," but that it is the offspring of the tape worm, undergoing one stage of its growth, through which it must pass before it can attain to the more dignified development of its parent.
many cases the cystic worm has the power of developing, at this stage of its growth, a large number of creatures resembling itself, and these have, each of them, the power of developing themselves into tape-worms. "The cystic worm—let it be an Echinococcus—has originated from the egg of a tape-worm, the embryo of which has found its way from the stomach and intestines, through their walls, into the tissues of the body. This worm consists of a vesicle or bag, to which is attached a head, called the 'scolex.' In Cysticercus, the hydatid of the pig, there is but one scolex, but in Echinococcus there are many scoleces. Now this scolex, or scolex-head, as it is sometimes called, is the stock or germ—the head—from which all the segments of a tape-worm proceed. The cyst of Echinococcus, then, has the power of producing a large number of these heads, each of which may grow into a tape-worm. The cyst—the original cyst of the worm—is, in the language of STEENSTRUP, a 'nurse.' KÜCKENMEISTER and the Germans call it a mother cyst, but this cyst will produce not only scoleces-heads, but other cysts like itself. These are 'daughter cysts'; and these secondary cysts will also produce scoleces-heads. They are also 'nurses,' and in virtue of their existence the mother cyst becomes, in the language of STEENSTRUP, a 'parent nurse.' The second cyst may contain, as it frequently does in the Echinococcus alveolaris of KÜCKENMEISTER, a third cyst—a 'grand-daughter cyst,' which is also a 'nurse,' and thus on." (LANKESTER, in Preface to his Trans. of KÜCKENMEISTER, &c.)

4. Neither of these cysts nor scoleces-heads have any sex. Nor do they acquire sexuality as long as they remain in the flesh in the hydatid condition; and to this state of the worm Professor HUXLEY applies the term 'agamous.' In order to acquire the conditions necessary to the development of sexual organs, the cystic form of the worm must be swallowed by another animal. "The scolex-head then becomes, in its turn, truly a 'nurse,' and this of a most prolific kind; for, the cyst below being displaced, the numerous segments ('proglottides,' as they have been called) begin to make their appearance. The conditions are now such, that sexes appear; each segment is merely a capsule containing a male and female generative apparatus, and nothing else. Eggs, the result of the union of sperm-cells and germ-cells, are now produced in myriads. These pass into the external world, and, being swallowed and digested, set free the embryos, which again become cystic, as above described." (Op. cit. p. xii.)

5. These phenomena are not peculiar to Echinococcus. STEENSTRUP observed them in the meduse, the cleavage polypes, the salpinx, and the trematode Entozoa. Professor OWEN has also added similar cases, in the exposition of his views on "Parthenogenesis," or the successive production of procreating individuals from one ovum, or sexual reproduction. Not only are there among the lowest animals, in various stages of development, capable of producing buds, or individuals like themselves, without sexual union, and embodying eggs, but there are also amongst the articulates, both in the crustaceans and insects, females producing eggs, which proceed to the development of perfect animals without any sexual intercourse, or union of sperm-cells and germ-cells. Such a phenomenon is so opposed to the general opinion as to the necessity of sexual intercourse for the development of the embryo in the higher animals, that many have not hesitated to express their disbelief in it. DR. LANKESTER thus expresses himself respecting it:—"Regarding, however, the phenomena of reproduction from the point of view afforded us by the entozoa and other forms of lower animals, we must receive the facts in both cases equally cautiously, and judge according to the evidence. Von Strentz, in his work on 'True Parthenogenesis,' affords good evidence for believing that the queen bee deposits two kinds of eggs, the one of which has come under the influence of the sperm-cells of the male, and the other not. A very curious point in this history is the fact, that whilst both eggs produce young bees, the impregnated eggs produce worker female bees, whilst the unimpregnated eggs produce male or drone bees. In a recent communication to the Royal Society, Mr. LUBBOCK has shown that species of the entozoostracous crus- maticous genus Daphnia produce living young in all respects like their parents, without any sexual intercourse. It would appear, then, that an as high as the most developed forms of articulate animals, we have evidence that there is no real difference between the functions of reproduction and generation." (Op. cit. p. xiv.)

6. THE ORIGIN OF ANIMAL PARASITES, more especially of the worms which often infest the human body, has long been a subject of speculation among naturalists and physicians. One class of writers believed that these parasites—at least many of them—originated in the endowment of animal molecules with virility from the parent body, favored by certain states of the vital forces of that body.*

* DR. LANKESTER, for the better understanding of these and other general remarks he has offered, has added the following diagram:

---

* The word 'Scolex'—scolec, Worm, or Spielwurm, German— or round worm, was employed by Miller to designate, generally, imperfectly developed forms of tape-worm. 'The head' was the most characteristic part of these creatures, and gradually the term 'scolex' was applied to the heads of all forms of cystic or tape worms. The term 'scolex' has no generic signification, as the creatures to which it was applied were immature forms of other genera. (LANKESTER, in Preface, &c.)
WORMS — THE ORIGIN OF.

body, the states originating their organization also promoting their growth and propagation. Since the progress of microscopic research consequent upon the improvement of our instruments, this doctrine, which till then had been gaining ground, has received a signal overthrow, chiefly at the hands of Geinitz. One of the most recent and of the ablest of these, remarks on this topic, " that he has gradually arrived at the conclusion, that these parasites do not originate by 'equivalen generation' from substances of a dissimilar nature; and physicians and naturalists thought themselves justified in assuming that the parasitic worms in the intestines of men and animals owed their origin to ill-digested nutriment, or that they were developed in the most widely different organs from corrupt juices. They took it for granted, that certain morbid processes in any organ were competent to give rise to parasites, assuming that the elementary constituents of an organ affected by disease, separated themselves from their natural connection, and not perishing, but transforming themselves into independent organisms, became parasites. It was certainly more convenient thus to speculate, than to endeavour to attain it by patient research and careful experiments, and the insight into the hidden workings of nature. It was by the latter method that the hitherto unanticipated development of the sexual apparatus was discovered in many parasites, such as round worms, thread worms, tape worms, and flukes, in which such an immense mass of eggs and young can be generated, that it seems unnecessary to look further for their origin. As to tape worms, it is well known that a single individual is often composed of many hundred joints. Each joint is capable of laying many hundred ova, so that the number of the progeny of a single tape worm is enormous. Dr. Eichenmuller of Copenhagen (Das Physische Leben in Popularen Vortragen; Berlin, 1852; pp. 112, 115) possesses a tape worm expelled by a patient of his, which consists of 1000 joints; and some of the joints contain more than 1000 ova. According to this writer, a careful examination of the reproductive apparatus of the adult shows the number of ova to be innumerable." (Von Steirold, Op. cit. p. 4.)

7. The precise mode in which such an immense brood of these parasites make their way into the interior of animals was long imperfectly understood. It was, however, ultimately ascertained that intestinal worms undertake emigrations in order to reach that animal whose organs are fitted by nature for their habitation. Von Steirold states that the young of the tape worm (which inhabits the intestine of the higher animals only), "leave the place where they were brought forth, or laid as eggs (that is to say, they emerge from the intestine of their parent's host), and seek an opportunity to enter into the intestine of some other creature. It is easy to convince oneself of the emigration of the tape worm, by examining the excrement of animals infested by them, at those times of the year at which they attain their sexual maturity. We then observe that sometimes single joints, or connected series of joints, full of ova, sometimes immense masses of the ova, are passed with the feces. The same thing holds good with regard to the ova of the Distomata that infest the livers of our ruminating animals; their eggs, after they have been transferred from the liver to the gall-ducts, being washed out with the bile into the intestine, and evacuated with the dung. These emigrations of the young of the intestinal worms benefit not only the creatures they infest, but themselves. There are many kinds of intestinal worms whose eggs the embryo is never hatched, if they remain in the place where they have been laid."

8. The description (German like) given of the accidental, but frequent, ingestion or passage of the ova of parasites into other animals, and the dignifying of this passage into an emigration, as if it were an act of instinct, imparts an air of imagination to what is nevertheless the fact of the frequency of this passage, and of its consequences. This writer states that these parasites "must wander to some other place in order to develop their young, or to allow of the escape of the young already developed in them. These young must then either wait for, or seek, an animal to lodge in, having entered into which, they are capable of attaining sexual maturity. By such emigrations the infested animals are at the same time freed from guests whose increase would be both troublesome and prejudicial. For example, what would happen if the millions of eggs that a single round worm or tape worm can produce were developed and generated in the same intestine in which they were laid? Would not the intestine, after the young had attained their full growth, and brought forth others in their turn, become at last so choked up as to disable this part of the digestive apparatus, so that the whole organism of the unhappy animal must perish along with his parasites." (Op. cit. p. 5.)

9. These emigrations and immigrations of the young of intestinal worms, or in less imaginative language, this discharge and passage of their ova from and into other creatures, are very important, though long an unregarded part of the history of their propagation; and numerous facts have been discovered showing that the origin of intestinal worms in the viscera of animals can be readily accounted for according to natural laws, without creative organs or "equivalen generation." An important circumstance favourable to the preservation and passage of the ova of parasites into animals in which they become developed, is the hardness of the shells which envelope them. Owing to this the germ or embryo of many of them are protected from external injury, and their vitality preserved for many months, and until circumstances admit of their development. After leaving the dwellings of their parents the ova pass into privies, drains, dust-heaps, &c., where, surrounded by more or less moisture, and subjected to various grades of temperature, and either raised in manure, or spread on fields and meadows, they are, either in the state of ova or in that of more advanced development, taken with various articles of food into other animals, or they are washed by rains into streams or brooks, and are swallowed in the drink. Many of the young intestinal worms, according to the digestive apparatus, or less developed, but still enclosed in their egg-shells, remain quite inactive in their passive emigrations, and it is of course a mere chance whether they reach their goal or not. The young of others, having left their egg-shells, may take a more active share in the process, creeping out of their holes and...
WORMS—THE METAMORPHOSES OF.

corners in wet weather, or in damp mornings, upon plants or grass, and enter animals suited for their habitation and development with the food. By preventing sheep from being driven out in the morning till the dew is off the grass, or from grazing in wet swampy pastures, these animals are so far protected from Strongyli and Distoecatia. The origin of the thread worm, known as the *Filaria insectorum*, that lives in the bodies of adult and larval insects, could not be accounted for, and was referred to equivocal generation; especially as they contained no trace of sexual organs. But Von Siebold ascertained that they were not true *Filarie*, but belonged to the peculiar family of thread worms, comprising the genera *Gordius* and *Mermis*; and that these parasites wander away when full grown, boring their way from within through any soft part of the body of their host, and thus creeping out. "These parasites do not emigrate because they are unsexed, or because the caterpillar is sickly, but from that same internal necessity which constrains the horse-fly to leave the stomach and intestine of the horse where he has been reared; or which moves the larva of the gad-fly to work its way out of the boles on the skin of an ox. These parasites creep out in order to become chrysalides, and thence to proceed to their higher and sexual condition." Now this desire to emigrate is implanted in very many parasitic insect larvae, and the perfect fullgrown, but sexless thread worms of insects, are in like manner moved by this desire to wander out of their previous homes in order to enter upon a new period in their lives, which ends in the development of their sexual organs.

10. As some kinds of parasites that have emigrated are never met with below a certain size, so some kinds that have already made their way into the interior of animals are not to be found under a certain size. It is known that many parasites do not enter into the animals in which they are to pass through their further stages of growth, until they have attained a certain degree of development elsewhere. This is particularly the case with such intestinal worms as remain parasitic in the last stages of their existence. When the *Gordicini* pass over to the *Gordicaceae* quit their parasitical life, in order to become sexually mature away from the animal they have infested. During these early wanderings, the worms in question, Von Siebold remarks, commonly undergo a change of form, often accompanied by other phenomena of so highly remarkable and abnormal a character, as to render their metamorphoses or phases of existence almost incomprehensible. By degrees a mass of observations of remarkable metamorphoses of intestinal worms accumulated and formed a complete class of seemingly irregular phenomena, until the Danish naturalist, Stenstrud, succeeded in evolving a certain order out of this confusion, by the discovery therein of a hidden underlying law of nature, by which all the phenomena that had seemed so devoid of plan could be reduced to order. He named this law the "*Alternation of Generations*". There are points of difference between it and *metamorphosis*; the first is, that the young of these animals which come under the former term are not only unlike their parent at first, but remain so; the second distinction is, that this young generation, so dissimilar to the parent animal, brings forth new creatures, which either themselves or their descendants revert to the original form of the first parent. Whereas, in simple *metamorphosis*, the dissimilar young pass by gradual changes into the likeness of the parent animal, and until this metamorphosis is complete are incapable of generation. Thus in the alternation of generation the parent animal produces a similar young, which Stenstrud terms "*nurse*", whose descendants only take her form. "An important circumstance which characterises these *nurses* or *Agramozoids* is physiologically is, the they bring forth young without themselves possessing any real sexual apparatus. Those *agamozoids*, in fact, multiply by division, by external or internal germinal formation; they develop within their bodies worms which become new creatures. But these worms do not deserve the title of eggs, nor the place where they are developed to be called an ovarium, since the worms which Von Siebold distinguishes by the name of *sperarium*, are not only devoid of the ordinary constitutions of an ovum, a vitelline membrane, yolk, germinal vesicle, and so-called germinal spot; but the further development of the germ-body is not preceded by those conditions which are essential to the development of the germ-body; in which, in certain agamozoids, the sex organs formed, cannot therefore be properly termed in ovarium, and I shall distinguish it by the name of *sperarium*." No "*nurse*" present any sexual distinctions, and hence their method of multiplication and propagation, which takes place by means of spores formed within *sperarium*, or by ordinary budding, or by division, must be arranged amidst the modes of asexual reproduction." (Von Siebold, Op. cit. p. 13, 14.) I must refer the reader to what this writer further remarks on the topic of alternation of generation, especially as it occurs among the *Trematoda* and *Cercariae*.

11. From his researches, Von Siebold infers that certain sexually matured *Trematoda*—*Mesonema*, *Distomum*—generate young within their sexual organs, which are not developed into sexual individuals similar to their parents in form and structure; but that each embryo is converted into an animal of remarkably different form—*Cercariae*, which has the nature of a sexual nurse, since without possessing sexual organs, it nevertheless generates young *Cercariae*. These *Cercariae* again differ from their parents, but gradually become sexually perfect, and in form and structure take the likeness of their grandparents. If we follow these *Trematoda*, which are subject to the alternation of generations, in their wanderings, we shall find that they meet with many obstacles to the completion of their developmental course, which is the entering into the viscera of an animal in which they can become sexually developed. The destruction of the various forms of *Trematoda* by the untoward circumstances to which they are liable, is compensated by the fact that they are furnished by the alternation of generations with the means of greatly multiplying the various developmental stages of their descendants; a sufficient number of "*trematodes*", remaining out of the numerous young of the nurse and larva, which achieve the propagation of their species.

12. The history of the *Cercariae* explains many phenomena erroneously interpreted by the supporters of the doctrine of equivocal generation. It was
difficult to understand how living entozoa could have originated in the viscera of animals, sometimes in organs deeply seated or cut off from all external communication, and could there propagate their kind; the mode of origin—by equivocal generation—assumed for them, apparently accounting for the circumstance of these entozoa being unprovided with sexual organs. Frequently also, young or imperfectly developed intestinal worms were met with in the substance of organs, and were attributed to equivocal generation, "though in reality these entozoa were in the act either of migrating, or immigrating, or else were tarrying until the creature they infested should be swallowed by some other animal, when the passive immigration for which they waited would take place. Many wandering parasites are unresistingly suffered to bore their way into and remain in the organs of animals, whilst certain kinds are stopped by becoming enclosed in a coagulable lymph thrown out by the organs they traverse."

There are two kinds of cysts connected with parasitic worms: in the one the cyst is thrown out by the parasite itself, as in the case of the Cecarria; in the other, the organ in which the encysted parasites lie embedded furnishes the walls of the cyst. In such cysts or capsules are found the most diverse kinds of intestinal worms, whose further course may be very various. "Many of the encysted young of intestinal worms experience no further change, but only remain for a longer or shorter period until such time as they may, together with their host, pass into the intestine of some animal of prey suitable for their future development. To this kind belong the Cercariae already mentioned. There is also a small, imperfectly developed, round worm, hitherto always erroneously described as a perfect intestinal worm, under the name of Trichina spiralis, which remains a long time in its cyst without either growing or developing sexual organs. This minute Trichina spiralis is met with not only in the substance of the muscles of man, but also in the pleura and peritoneum of the most widely different kinds of vertebrate animals, enclosed in oval capsules about the size of a pin's head, and lying, for a certain time of confinement is allotted to this little worm, and its deliverance not effected, it dies and undergoes a process of calcareous degeneration, its form being altered or entirely destroyed. Other encysted intestinal worms succeed in obtaining nourishment through the walls of their prison, and thus go on growing. Those, however, which are intended by nature to attain their sexual maturity only in the digestive organs of certain animals, cannot arrive at this condition in their cysts, and must, notwithstanding their further growth, fail in the attainment of the power of sexual propagation; this is deprived of many by the predestined creature whose intestine is alone fitted to allow of the passage of these sexual intestinal worms into the last stage of their development. (Von Serboli.)"

13. From what we have stated we gather that those species of entozoa that have a nidus in these of these organs of certain mammals, must pass through the stage of infancy, and attain sexual maturity only in the definitive organ of digestion of the definitive host, and that they are unable, if placed in a foreign organ, to escape the perils that await them there. The embryo parasites that have only just left their eggs disperse in all directions, so that they may immigrate into other animals, whenever an opportunity offers. Many thousands of these embryos of necessity never attain their object, owing to the numerous casualties they are liable to. However we may accept the facts displayed in the researches of Von Sersoli and others, it by no means follows, that the emigration or immigration of these parasitic animals is the result, as they suppose, of instinct. The parasite having arrived at the full stage of sexual development produces numerous ova, many of which necessarily are so circumstanced, by situation, dissemination, &c., as to admit of their passage through the different phases and metamorphoses of evolution and development; but that these changes, and the emigrations resulting from the circumstances common to all or most of them, admit of the inference that instinct has anything to do with the phenomena, or that their temporary or continued residences, their journeys or passages from one place or animal to another— their migrations, &c., proceed from their possession of this endowment or principle, or that their migrations and residences are otherwise than altogether passive, cannot be received or credited without further evidence. But, after thus stating a disbelief of the instinctive faculties of these parasites, the facts put to the test with their propagation and evolution become practically of importance.

14. Instead of viewing the migrations of the embryo or young parasites as passive, and the accidents connected therewith as equally so, Von Sersoli considers the former as altogether instinctive, and the latter as stray migrations. But, whilst altogether disbeliefing that instinct has anything to do with the matter, this writer's views deserve consideration. The point of most importance, he remarks, is that these embryos should select, as their temporary residence, such creatures as will be consumed by those animals, whose intestines served their parents as a habitation and birthplace for their young. But many of these young, immigrated, intestinal worms will die without reaching the last stage of their development, in consequence of their host and involuntary carrier escaping from his allotted term of life. After a certain time of confinement is allotted to this little worm, and its deliverance not effected, it dies and undergoes a process of calcareous degeneration, its form being altered or entirely destroyed. Other encysted intestinal worms succeed in obtaining nourishment through the walls of their prison, and thus go on growing. Those, however, which are intended by nature to attain their sexual maturity only in the digestive organs of certain animals, cannot arrive at this condition in their cysts, and must, notwithstanding their further growth, fail in the attainment of the power of sexual propagation; this is deprived of many by the predestined creature whose intestine is alone fitted to allow of the passage of these sexual intestinal worms into the last stage of their development. (Von Sersoli.)"
the muscular substance, the liver, or the peritonæum; here they remain undeveloped, whilst other individuals of the same brood, which have found their way into the intestines of the same animals, arrive at maturity. "The Trianënorhus nodulosus, infecting fishes, offers an example of this. Developing in the mouth, it becomes a tape worm, in the intestines of pikes and perch, whilst, at the same time, these fishes often harbour other tape worms, which are, however, always sexless, in cysts in their liver. These last must certainly be also regarded as strayed parasites."

15. Von Siebold believes that, in the bodies of vertebrate animals, the small embryos of intestinal worms bore their ways not unfrequently through the walls of the bloodvessels, and fall into the current of the circulation, and are carried thus to distant parts. Embryos of intestinal worms, to which the term hematozoon has been given, have often been discovered in the blood of birds, reptiles, and fishes. These hematozoa never increase in size, nor become further developed in the blood, but often stick in the small bloodvessels of organs, which afford a more congenial soil for their further growth, and hence appear, by some occasions, worms in the brain, in the spinal marrow, and in the eyeball of man and animals. The Cyrtocercus cellulose, the Canopus cerebralis, and the Echnoæocus hominis and veterinorum have been occasionally found in these situations, and have served as an argument for the doctrine of equivocal generation. "With the migrations and alternation of generation amongst the intestinal worms, two other phenomena are connected, which were formerly quite unnoticed, but which now have been generally observed. In the vicinity of those sexually perfect intestinal worms which, in their wanderings, are subject to the alternation of generations, only eggs, or recently hatched embryos, are met with; but the further stages of development are always wanting, since they first make their appearance after the emigration of the young to other places. Further, many of these intestinal worms, taken whilst in the act of migrating, are never found below a certain size, since they do not commence their wanderings, either as nurses or larvae, until they have already reached a certain stage of their development." (Op. cit. p. 30.) Would it not be more correct to view these evolutions of parasites from genus and ova, and their passages, or passive migrations, during their development, as accidents connected with the numbers generated, and with the locations and transitions of the embryos; their development and sexual perfection being results of favourable circumstances which happen only to a few of the many generated; instead of viewing these migrations and their consequences as events produced by the instinctive endowment which Von Siebold has conferred on these parasites? Whilst the possession of this endowment by these animals may be disputed, the facts adduced by this writer, respecting their origin, development, and alternation of generations, are more deserving belief and consideration.

16. The Classifications of Intestinal Worms have been so numerous and so different the one from the other, that an attempt to place them before the reader would not be consistent with my limits and with expectations of utility. Recent researches also, have thrown doubt on the principles by which the older arrangements were guided; and the orders, genera, and species of Entozoa, which have been found in the animal kingdom, are so numerous as to prevent even a brief notice of them at this place. I must, therefore, refer the reader to the more recent arrangements enumerated in the Bibliography, and especially to those of Dr. Joy and M. Felix Dujardin. Dr. Küchenmeister has given a classification of animal and vegetable parasites, which, as far as it refers to the human Entozoa, I shall, with some alterations, adopt.

18. I. Class. The INFUSORIA are destitute of high organisation. They are simple, vitalised, membraneous structures, often several dozen in number. The vibriones, the bursarie, monades, and flagellules, are peculiar attribute of fermenting and putrefying food animal substances, or always presuppose a half-dead soil, and do not derive their nourishment so much from living substances as from matters which the living body has expelled, or are in the course of expelling as foreign bodies; they are properly only to be regarded as indirectly parasitic upon the human body. FICINUS found sluggish bean-shaped Infusoria up to an inch, and sometimes double this size, and affixed a globular form, in the perspiration of the feet, on the places where the epidermis was thrown off, as well as on the moist folds of the skin of young children; and others have met with them in pustules and pustules and foul secretions from the vagina, urethra, bladder, putrescible urine, &c.

19. i. Trichomonas (HAGARDEN). T. vaginae.—"Corpus nodulosum, gelatinosum, lacertum; cauda brevis; corpus variopontum; Motus vacillans. Longit. 740." This parasite occurs only in women with gonorrheal discharge, or with an abundant vaginal secretion containing mucous and pus globules, and never in a healthy vaginal secretion. KöLLIKER and SCANDZEN found it in the vaginal — never in the cervical — secretion of both pregnant and unipregnated women, especially in the creamy and acid secretion, sometimes in the neutral, but never in the alkaline. Owing to its resemblance to the mucous corpuscles, it has been confounded with them. The body of this parasite is 0'001—0'018 millim. in length; the flagellum, 0'028—0'08 millim. in length; and furnished with 4—8 short cilia, in continual movement, which facilitate its recognition. The capability of infection by these Infusoria has not been determined, although very probable.

20. ii. Denticola hominis (FICINUS). "Genus valde dubium" (Küchenmeister). — This parasite, according to FICINUS, is an acellicated Infusorium, with the mouth on the ventral surface, and probably furnished with a carapace, resembling the parameria and kolpoda; but he considers it more allied to the monades and vibriones. The genus he believes to be numerous; and he infers...
that every mammal has its peculiar species. Dogs and horses, he says, next to man, exhibit these In-fections the most finely. The worms, especially in the intestines of the mollusks;
more rarely on the mucous membrane of the mouth, scarcely in the saliva; but most abundantly where the teeth have been neglected, and in hollow teeth. They adhere, form filaments, and entwine themselves about the gums, pushing between the roots of the former and the latter, destroying their union. These effects are, however, prevented and remedied by the usual operations on the teeth, and by aromatic, tonic, astringent, and antiseptic dentifrices.

21. 2nd Class. - a. Vermes, helmintes, are of the greatest importance to both the pathologist and the practical physician. The parasites belonging to this class are destitute of many of the organs possessed by the higher animals. They have no distinct respiratory organ; the oxygen necessary to their existence can only be taken up in their fluid food. Hence they are enabled to exist within the human body, either in its closed or open cavities, or in its tissues. "They constitute the true Entozoa, and furnish no representative to the series of human Epizo, although some of them may be destined, in the course of their development, to pass a portion of their lives in water, or perhaps (as in the case of the Cerca-vic) as Epizosa upon other animals. Sexual organs may always be detected in those specimens of these animals which have attained their last grade of development." The sense of sight, smell, and taste are wanting in all these parasites, but their sense of touch appears to be highly developed. The intestinal canal is wanting in the Cestoida. In the Trematoda it forms a cavernous canal, in which the mouth also performs the functions of the anus; whilst in the Nematoidea it becomes a complete alimentary canal, with a mouth, cesophagus, stomach, intestine, and anus. In the tissues of the Cestoida is a tendency to the formation of an envelope of a calcareous nature, which is wanting in the Trematoda and Nematoidea. These three kinds of true Helmintha are characterised, 1st, By a general sense of touch; 2d, By a muscular system of four longitudinal lateral canals in the Cestoida, of which Trematoda, which are less distinctly marked in the Nematoidea; 3d, By a muscular system, composed of transverse and muscular fibres, without transverse stria; 4th, By the structure of the epidermis, which consists of a homogeneous finely checked substance, closely approaching the character of chitine; 5th, By the property of giving off a strongly refractive, albuminous substance, in oleaginous drops, when in contact with water; and 6th, By their scarcely effecting their development without a passive and active migration of their embryos and immature colonies.

22. b. As to the last of these characters, Kuchenmeister, more rationally than was stated, as shown above, by Voss, Stenold, remarks that "this migration itself is passive during the embryonal state, and as long as the embryos are still enclosed in the egg-shells or envelopes, during which period they are usually eminently passively, into the external world, generally with the excrement of the hosts or their parents; and then again, passively in general, into the intestinal canal of the animal, in which they are to acquire a higher de-

velopment. From the latter moment commences their active migration, by which they seek the situations, usually, which are most advantageous to the intestinal canal, in which they are to undergo their metamorphosis into the next higher step or steps of development, which is generally accompanied by an encysting process. Finally, as a general rule, at least as regards the trematoda and cestoid worms, they become detached from the utero-oogenic sac, its exclusive possession, the intestine of the animal in which they are to attain maturity; that is to say, they must pass with the food of their new and final host into its intestine." (Op. cit. p. 4.)

23. c. General pathology shows that the worms cannot effect their active migration without causing some irritation of the regions through which they pass, whether this migration is performed by the youngest brood, as is usually the case, or by the more or less mature animal, as rarely occurs, and chiefly among the Nematoidea. The passive migration of all immature parasites into the human intestinal canal takes place without any perceptible morbid phenomena.

24. d. The general prognosis of this class of parasites may be stated as follows: 1st, The young animals engaged in their migration are the most dangerous; 2d, Next to these, the migrating mature individuals, which inhabit the intestinal canal, produce the most dangerous symptoms; 3d, The animals which reside in cysts or closed cavities can become dangerous only when they attain an enormous size; but, when small, they may be present without doing any mischief; 4th, Most of the mature individuals are more accessible to curative means, than those of lower stages, especially those which live outside the intestinal canal.

25. e. The principles of treatment for the Helmintha are 1st, The destruction or removal of the mature worms, and of their prophy; 2nd, The observation of a rational prophylaxis, founded on the modes of life and migrations of the immature individuals; on the constitution and circumstances, and the habits and modes of life, of people subject to these parasites; and on a knowledge of the nature and peculiarities of the situations in which these plagues are endemic.

26. 111. The arrilves of which I have now to treat belong to the first sub-class of Diesing - Helmintha achathehelmintica: animanta evehetata, inarticulata (i.e., extrematibus articularibus nullis praedita), nunc mollis, aut elasticis, ebraniqata, setis retractabilis nullius. I have, following Vooit, Winchow, and Kuchenmeister, divided this class into two divisions - 1. Platynema, flat worms; and ii. Nematoidea, round or thread worms; and again dividing the first section or order into 1st, The Cestoida, Vooit, the Cephaloceleus, Diesing; or the Platynema coloniae exhibitant, or flat-worm colonies, of Kuchenmeister; and 2nd, The Trematoda, Voigt; Myxozoida, Diesing; or Platynema isolata, isolated flat-worms, Kuchen.

27. i. Order, Platylaelmia. - Entosa solitaria aut composita, androgynum. Corpus depressum vel teretium, mole, organi ad fivandum apti. Anus maturitatis. Anus undivisis, divisis (vaginas semplo), aut nullus. Cavitatem corporis non distincta. Metamorphosis in plerique; larve geminare aut sporadica. (Leuckart.)

28. A. Sub-order, Cestoida. - Cephalocele-
WORMS—GENERATION AND GROWTH OF TAPE WORMS.

out in the foreign soil into a vesicle, without developing sexual organs.

30. In 1850, Van Beneden, the Belgian zoologist, declared the vesicular worms to be larva-like, or young states (scutellae) of Tenea, and compared them with the larvae of Tetrathyridium. According to him, the head of the tape worm (scutellum) is produced from the egg of the tapeworm. If an egg of a tapeworm reaches the intestinal canal of an animal in which it may be further developed without interruption, the jointed mature tape worm (strobila) immediately grows from the egg in uninterrupted succession; but if it does not reach an intestine of this kind, a longer or shorter period of rest ensues in the further development as soon as it has arrived at the evagination of the head of the tape worm (scutellum); in this case the anterior part of the head sinks into its inflated hinder part, and it becomes a Cysticererus, or a cysticerical asexual form. Kiechmeister, however, finds two errors in this inference. 1st. It is not proved that a tape worm can pass through all the phases of its development in the intestines of its host; and 2nd. And just as little as the caudal vesicle is produced subsequently by dysposical degeneration (Diener and Von Stauroth), the ready-formed head sinks into its inflated hind part, in order to become a Cysticerus.

31. As Goeze had suggested in 1780, Kiechmeister, in 1851, administered various cystic worms to different animals. For this purpose the latter selected the Cysticerus piaformis of the rabbit, and also the C. fasciolaris, and gave the former to the dog and the latter to the cat, and in the intestines of both these animals he succeeded in rearing tenmin rapidly approaching maturity. From these experiments he makes certain deductions, of which the following are the most interesting:—1. The caudal vesicle occurs in all individuals of all species of cystic worms, even though they live in the most various zones and different animals. 2. The universal loss of the caudal vesicle has its analogue in the metamorphosis of many animals. 3. All cystic worms, in the majority of their existence, have the head constantly inverted towards the caudal vesicle. 4. The state of rest in which the cystic worms must live in the interior of their caudal vesicle, in order to their development, would be inconceivable, if they had to collect the nutritive fluid for themselves, and did not contain it in them. 5. The cystic worms are not strayed dropical tape-worm-nurses, but tape-worm larvae furnished with a provisional organ (caudal vesicle), probably being a reservoir of nourishment, and incapable of sexual multiplication, for which there is neither room nor sufficient nutritive material. 6. Same opinion was held in France. At first, however, Von Strobel inclined towards Steenstrup's view, and said:—"In its form, its suckers, and its circle of hooks, the head of the asexual cystic worms possesses such a striking similarity to the heads of certain tape worms that it is tempting to believe that the cystic worms are nothing else than undeveloped and larvo-form tape worms." He subsequently, nevertheless, arrived at "the most decided conviction that the cystic worms are strayed tape worms which have remained undeveloped and become degenerated, and of which the body grew..."
MEISTER asserts that all eminent German zoologists now agree with him in believing "that everycestode worm, and not merely the Tania, pass through acystical state; that the cysticercal larvae live in various parasen organization organs, and the free scolices (strobila) usually in the intestine of a different host. Usually, that the tape-worm head (gland), is produced in the interior of the previous embryo body (i.e., the caudal vesicle), and remains enveloped by this until it gains the situation for which it is ultimately destined."

32. But to place beyond all doubt that the cystic worms were necessary steps in the development of Tania, it was also requisite to prove their production from the embryos of the tape-worm brood. "It is true that the six characteristic embryonal hooklets have not yet been detected upon true vesicular worms, but we shall shortly see that the laws of analogy, as well as experiment, afford us a glimpse into this process." After various experiments, KÜCHENMEISTER proceeds to state that he resolved to resume those experiments with the Tania Canum in order to obtain the remarkable phenomena of the vertigo in sheep. On the 16th of May, 1853, he obtained the cystic Cenuri; on the 25th of July mature proglottides of the Tania were passed by the dog, to which the Cenuri were administered; and these, in order to make the experiment under the most unfavourable circumstances, were administered to a perfectly healthy two-year-old wether, a description of sheep which are usually free from Cenuri. On the 10th of August the sheep was vertiginous; and on the 13th it was necessary to kill the animal; and in the brain he found fifteen young vesicles of Cenuri, partly on the surface of the brain, which was reddened by inflammation, partly in the substance of the brain, and even in the ventricles. In January, 1854, six lambs were fed with Tania Canum. Of these, five became vertiginous in about eleven days. LIECKE, fed, in October, 1853, a colony of white mice with Tania cruscolis. In January, 1854, he examined his mice, and found them infested by cystic worms. KÜCHENMEISTER subsequently proved the accuracy of the opinion more strongly, and VAN BENEDEN proved it, after DURANDIN had described the segments of tape worms which occur isolated, as peculiar animals, under the name of proglottis.

35. "1. Mature Tania have hitherto been reared successfully from all vesicular worms administered when a suitable host was selected; thus, from Cysticercus pisiformis the Tania serrata vera was obtained; from Cyst, tenacialis, the Tania en Cyst, tenacialis; idem from Cyst, cervicalis, the Tania cerviciae;—all three in the intestine of a dog; from Cyst, fascicolaris, the Tania cruscolis, in the intestine of the cat; from Cyst, cellulosae, the Tania solitum, in the human intestine: from Echinococcus stercoralis, the Tania solitum, in the human intestine: from Echinococcus ceto nominem (Scoticharnia of KUCHENMEISTER), a Tania Echinococcus, in the intestine of the cat; from Cyst, longicolis, Hyperchei, the Tania cruscolis, RUD., in the intestine of the dog (LEUCKART)."

34. "2. From the eggs of Tania solitum in pigs, from those of T. Canum in sheep and cattle, of T. serrata vera in rabbits, of T. crus-
fore in a mass, solitary or numerous specimens of a cystic, or of the analogous state, are produced within one and the same host." The proglottides thus perform an active migration from the intestine of their previous host, and are positively or contingently transferred into the intestinal canal of a new host. With the dissemination of their brood, their function ceases.

37. iii. The six-hooked brood, enclosed in separate egg-capsules. These are called eggs, although their development differs greatly from that of ordinary eggs. The embryos enclosed in the egg-shells are globular naked vesicles, unlike their parents; the smallest of them measure only 0.022 mill., and the largest, 0.05. They are destitute of any organs, possess an epidermis with a double outline, and usually bear six, but in the Tetrarhynchus only four, very small microscopic hooklets on their anterior extremity, so that they carry their destination, that of boring forward through the tissues, as it were, written on their foreheads. The bodies of these small but very dangerous vesicles, whether armed or unarmed, are always capable of motion. The embryos which are destined to migrate into cold-blooded animals are more or less in the presence of larger hooklets, and exhibit distinct movements in the usual temperature of a room. Those destined for warm-blooded animals are much smaller, with smaller hooklets, and exhibit distinct movements only about the temperature of the stomach. (Küchen.)

38. iii. The destiny of the six-hooked brood when not free. — A. What is the fate of this brood until it reaches its settled dwelling-place external to the intestinal canal? — As soon as the embryo becomes free in any part of the digestive canal of an animal which suits it, according to Vaz Bene-
dez, it brings together the central pair of its embryonal hooklets like a wedge, and at the same time, by thrusting and twisting, begins to force them forwards. Having in this way made a little progress, it assists itself further with the two lateral pairs of hooklets. Küchenmeister supposes that, having thus penetrated into the tissues, these hooklets are afterwards conveyed either into the liver by the vena portae, and remain fixed in the finest ramifications of the blood-vessels, or into the brain, or into other parts. The migration of the young of the Cestoides to the places where we meet with them as vesicular worms, or in analogous states, takes place in the following way:—

39. 1st. A portion of the six-hooked brood, in all species of Cestoides may reach their dwelling-place directly and by active migration, by boring their way. 2nd. Others, by an uncertain duration of this migration, reach the vessels of the new host, penetrate — (a) either become developed in these ramifications, the walls of the vessel becoming their envelopes; or (b) they migrate passively into the neighbouring tissues, after the rupture of the walls of the vessels, in consequence of the swelling of the embryo, or (c) after being thus retained in these ramifications they enter anew upon an active migration, passing into the tissues by means of their hooklets, and increasing in size.

40. What further takes place with the embryos when they have come to rest in their new dwelling-places? The third stage of the development of the Cestoides, consists of the so-called vesicular worms and their analogous sexual forms, "which, in accordance with the alteration which the embryonal vesicle undergoes in the different species of tape worms, and with the different animals infected by them, may be divided into cisticeroid (vesicular) forms, platycercal (forms with a flat, inarticulate, un-like appendage), and acercal (or tail-less), forms. It is a common peculiarity of all the three forms here mentioned, that they are cestode-heads pro-
duced from the embryonal vesicle, which occurs in the interior of the embryonal vesicle, or upon it, in a state of rest. We may therefore best comprehend this stage under the name of resting vesicles." The metamorphosis or transition of the embryos to the resting, and usually cysticercoid scoleces, may be stated as follows:—

41. 1st. "The embryo, still furnished with six hooklets, begins to swell by the reception of fluid (liquid nourishment), which is secreted from the place in which it has established itself: this is at first a fluid similar to protoplasm, but after the formation of the enveloping cyst, or after the cessation of inflammation, when the creature is free in the interstices of the host's tissues, it does not agree so much in its composition with the serum of the blood as with the ordinary products of the secretion of serous membranes." (Luechen.)

42. 2nd. As soon as the embryo has in the manner rapidly enlarged to a certain size, and arrived at a state of repose, the round vesicle is transformed, when it does not project freely into a serous cavity, and has not fallen into one, surrounding itself with an envelope, which protects it and assists it in procuring repose. These enveloping cysts constitute an absolutely new formation, which is analogous to serous membranes, and which constantly increases in size with the growth of the young cestode vesicle. When, however, the brood of a cestoid worm gets freely into serous cavities, it either never attains the formation of an enveloping cyst, or does so at a rather late period, and at a time when the young embryo has been, and is in a suitable available size, and often exhibits the Tenuis head as an advanced state of development. In places where the young cestode worm again falls into repose, a fresh exudation of plastic matter adapted to the formation of cysts takes place, the walls of the cyst being rich in blood-vessels. (Küchen.)

43. 3rd. By the reception of the secretion of the serous membranes, the young cestode vesicle swells up. At its anterior end, and at the point where the six embryonal hooklets are situata, a funnel-shaped pit is at first formed, and this gradually penetrates more deeply into the parenchyme of the vesicular body. In the bottom of this pit the first traces of the head appear, whilst the lateral walls of the depression become converted into the body — the central body — of the future cestode worm, and the remaining portion of the embryonal vesicle, which is not inversed, or not implicated in the metamorphosis, becomes the so-called vesicular vesicle. The invention of the first formation of the head most frequently commences at the anterior surface of the vesicle, and are seen distinctly in the cestodes of Atria empi-
corum, for in these the six small hooklets are placed in pairs at the point of transition of the central body into the caudal vesicle of the worm. The
central body and the head are always developed in the interior of the embryonal vesicle, and during the whole period of the vesicular state the head always has its apex directed towards the caudal vesicle, even when the central body, which encloses the head in the form of a hollow canal, has not sufficient room in the embryonal vesicle, but is forced out of it by the growth of the latter. 114. 4d. From the experiments of HÄNNER, KÜCHENMEISTER, LEUCKART, ROLL, VAN BENEDEN, ESCHICH, &c., with the various Teniae which pass through a vesicular condition, the following appears:—According to LEUCKART, at least in experiments with T. serrata, we find twenty-four hours after administration the six-hooked embryos in the blood of the large abdominal veins, especially the vena portae; and on the fourth day, in the livers of rabbits to which they have been administered, small, white, clear vesicles of 0.3 millim. in diameter, but rapidly increasing in size, which, on the earth, are already 1 mill. in diameter. In T. serrata the actual embryo, after the lapse of fourteen days, measures 1.5 mill.; in Canavus, it is about the size of a grain of millet at this period. The small vesicle (the worm), after it has begun to grow clear, acquires, in its interior, numerous large clear enucleate vesicles, which, according to LEUCKART, are similar to sarcode drops. In the parenchyma we recognise a cortical layer, which becomes thinner, and the cells of which are converted into mucous envelopes by fibroformation, and a medullary layer, in which elastic vesicles or cells occur in great quantity. From the appearance of the medullary substance, the growth of the little worm, which is capable of motion even before the muscular layer is developed, advances with rapidity. Even in the first fortnight, and shortly afterwards, the form of the young cestoidal worm varies according to the species. Some, such as the younger Canavus and Cystic. celatome, tenaculitis, and fasciolaris, are spherical; others, such as Cystic. platysoma, and probably also Cystic. longiodobis and fistulosa, are oval. Many of those seated upon the surface of organs, projecting into closed serous cavities, with the aid of a full ciliated stage are and finally fall into these cavities; the oval forms appearing to wander more than the round ones. About fourteen days after administration, the above changes take place almost universally and in all places. But those individuals which have not found a situation favourable to their development undergo a retrograde metamorphosis, passing " to the state of cæsæous, granular, or atheromatous masses, in which we may seek in vain for any remains of the embryo, although this certainly is present. Many cases of miliary tubercular disease of particular organs may indeed consist of nothing else than the dead, fatty, and cæsæous young of wormy larvae." 114. 5th. In the third or fourth week, when the young brood of Cysticerus platysoma measures about 2 mill., and that of the Canavus is of the size of a pin’s head, we may see, according to LEUCKART, beneath the epidermis a layer of mucous cells, followed by a fatty substructure, and then the medullary substance. At the point where the head is to be formed, a turbidity is produced by the aggregation of small nucleated cells, in the interface between the muscular and medullary layers. This is the first foundation of the head of the tape worm. Opposite to this turbidity a pit is observed externally, the inner wall of which is formed by the inverted epidermis, and which passes through nearly the whole depth of the globular foundation of the head; this latter appearing like a peg attached to the inner wall of the worm. In the central mass of the head, especially in its upper part, calcareous corpuscles appear, at first sparingly. Two or four vessels are also observed rising in a tortuous form through the upper part of the lobe, and passing over on the external sac-like envelopes. The vesicle now becomes larger and clearer, and the medullary layer, pushed against its peripheric layers, grows thicker, whilst vessels and calcareous corpuscles make their appearance, especially in the anterior part of the body, between the muscular and epidermic layers, but not in the former, in some cases before, in others after, the formation of the cephalic process. From the time when this process commences, the caudal vesicle ceases its activity in the true Cysticerus; its functions are then only passive, serving as a reservoir of nutrient, or as a protection to the head, which requires repose for its further development, and preserving sufficient room for this end. I cannot follow the descriptions of KÜCHENMEISTER and other helminthologists further, as respects the development of the head and its hooklets, &c., but must refer the reader to Dr. LANKESTER’s translation of the work of the former, and to the other works referred to in the Bibliography. I may, however, notice the following conclusions of this observer:— 114. 6th. In the progress of the metamorphosis of the six-hooked cestoidal brood into scolecites, it has been shown that a portion of the Teniae pass through a true cysticerical (bladder-worm) state, whilst the other part, without ever arriving at this state, furnish exactly the same structure (cestoidal heads—scolecites). This latter part KÜCHENMEISTER has divided into platycercal and acerical forms. (a.) True Cysticerus occur only in warm-blooded animals, especially mammals; and cysticeroidal forms principally in cold-blooded animals. (b.) The eggs of all Teniae which pass a cysticerical phase of development, are inferior to the platycercal and acerical forms in regard to the length and cylindrical form of the rostellum. (c.) Teniae with a cysticerical phase of development, are inferior to the platycercal and acerical forms in regard to the length and cylindrical form of the rostellum. (d.) Teniae with a cysticerical stage possess during this a highly developed receptaculum capitis, which forms a part of the future neck, and in which, as long as this stage lasts, the hooklets are introverted. The allied platycercal and acerical forms are destitute of the accumulation of fluid, and of the receptaculum. (e.) If the six-hook cestodal brood gets into animals which are not suitable to it, or into such organs in an animal already infected, it follows a fatty substructure, and then the medullary substance. On the point where the head is to be formed, a turbidity is produced by the aggregation of small nucleated cells, in the interface between the muscular and medullary layers. This is the first foundation of the head.
number of the cestoid embryos which become developed to the scolex state and are destroyed either by a natural or a pathological death. We only know that their life may extend even to several years; but inflammatory processes and alterations of the organs to which they are attached from the organs they inhabit, may destroy them more or less rapidly, and change them into masses consisting of cholesterol, calcareous, fatty, suture, and similar substances.

47. iv. The Scolex passing into activity.—On this topic I may now say that previously to recent writers, more especially to KüCHENMEISER, and notice merely a few of the more prominent parts of their descriptions. As a general proposition, it is inferred “that the animal infected by cestode worms is usually the source of food, or the prey, of that infected by tape worms.” The host of the cistic worm is devoured by a carnivorous predaceous animal, and by this means the cistic worm arrives, together with his previous host, in the stomach of the carnivorous animal. During the process of digestion, the enveloping cysts in which the cistic worms were enclosed, or, if the animal lived free in cavities, these latter, perhaps both, are digested, or are forced out, or are forced out only by the teeth of its devourer, when the cistic worm escapes into the cavity of the stomach. Here the worm extends itself; its caudal vesicle collapses. On the caudal vesicle and the middle of the body of the cistic worm digestion begins to set perceptibly. The body at the same time elongates and extends itself, but the head and the short neck are still inverted, as during the cysticercal state. But now the head and neck extend themselves. The head, the hooks still exhibiting the position of cysticercal existence, their spines being directed backwards towards the suckers, and their shafts towards the apex of the head, draws itself, as it were, towards through the neck, by turning itself inside out. As a matter of course, the whole worm is thus turned inside out; and the margins of the head and neck which were previously turned in, become the free outer sides of the worm. A portion of the cistic capsule is then cast off, with the body and the caudal vesicle, and a portion wraps itself into the funnel-shaped constriction of the young Tenia.

48. At various times, sooner or later, according to the evolution and age of the cistic worm, the formation of segments commences and with this, consequently, this stage of development is concluded. It should be recollected that Tenia cannot be reared from such scoleces as do not exhibit perfectly developed hooks. They die immediately. The first transformation of all cistic worms introduced into the intestines of a warm-blooded animal takes place in the same way; but the process stops before the commencement of segmentation, in those cases in which the intestine of the animal in which the vesicular worm has arrived is unfavourable for it and its future development. Thus circumstanced, it lasts but for a short time, no trace of it remaining a fortnight after. The first formation of the platycercal forms immature Cestodea takes place exactly like that of the cysticercal forms: in the aceral forms no casting off of a portion of the former embryonal vesicle takes place, but the whole of it is retained, and the formation of segments commences immediately upon it. It still remains to consider—How the scolex, after entering upon its activity, becomes converted into a tape-worm colony—Stróbile.

49. v. The Stróbile, or the so-called tape-worm colony.—“Immediately after the healing of the cysticerc on the neck and on the former receptáculum capitis, the scolex betwixt the anterior end of the head and this cysticerc a budding forth of the body, produced without sexual propagation, and which becomes constricted into segments by transverse furrows or wrinkles. By the constant production of new masses on this plan, the unist bíria is continually pushed further back, so that this cysticerc is at last removed to a considerable distance (varying according to the species) from the head. During this time the individual segments increase, and grow in the same ratio as their removal from the head; they at the same time acquire sexual organs, male and female, in each segment, and which are very rarely, and probably never wanting in the colony. Finally, when they have attained a sufficient size and maturity, they produce the embryos (§§ 41, 2.), and last of all cast themselves free in the form of the proglottides (§ 36.). If we were to give a definition of the stróbile—it is a series of joints, or individuals, wide from the egg, from the scolex in the space between the part of the latter that must be called the head proper, and in certain extremity, by a sexual reproduction; which are in direct union with the scolex, and which, when examined from the anterior to the posterior, present sexual segments, half and fully formed sexual segments, and segments engaged in sexual reversion, the last of which have become truly independent individuals.” (KÜCHENMEISER, Op. cit. pp. 84–5.) Thus we have seen how the segments with their ova and embryonic structure, are developed; and, when they have become the hindmost of the colony, cast themselves loose.

50. My limits admit not of a full description of the minute structure of the fully developed Tenia. It will be found in the work just quoted. I may, however, briefly state that no digestive apparatus has been found in these animals. Most writers assert that up to this time the parts of the body are detached in them; but HUXLEY states that a single ganglion is situated in the axis of the head, and that it sends off nerves to the suckers in some Tenia. The most important points are the dissemination of coelomocytes corpuscles in their structure, and the formation of circulating vessels. With the development of the scolex it was seen that a number of four principal lateral vessels takes place in the head, and that smaller branches are given off from these trunks. These vessels probably open outwards near the receptáculum capitis or neck, or about the situation of segmental production; but the ultimate structure, connection, and termination of these vessels have not been precisely determined. The muscles consist of transverse and longitudinal fibres, which may be recognised most readily in the neck. The suckers, peculiarly muscular parts, present radiate fibres uniting in the middle of the sucker, under which lies a layer of circular fibres, and the retinacula. It has not been ascertained whether or no muscular fibres run to the hooklets of the embryo. The hooks of the Tenia appear to ride upon the skin or integument, or in slight impressions. The movements of the hooks seem to be produced by changes in parts of the head, particularly of the retinacula. The sexual organs,
both male and female, exist in each segment, in which numerous eggs are produced. A very
minute description of these organs, — the penis, testes, vagina, uterus, &c. — is given by Küchen-
meister.*

61. The Cestodea, or Cestode worms, occur
in man either in the mature state, and then in the insensate form (Bothrioccephalus latius, Tania me-
dianenella, Tania nana); or in the larva or scolex state (Cysticercus visceralis seu tenaculis. Echinococcus veteranorum, seu scoleciarium, E. hominis seu alterricaprae); or lastly, in all
known stages of development (Tania solutum and Cestodes cellasses). Küchenmeister defines this genus,†

* The developmental history of the Cestodea may be understood, if considered as follows:
7. The mature sexual animal, which is produced by sexual generation, separates from the colony as soon as it has attained its majority, migrates actively from the
host to the new host of its choice, and thence passively into the stomach of another usual
herbivorous animal. It bears within it —
11. The germ-nurseries or embryos produced by sexual
and, when possible, by asexual reproduction, flourish with four or six hooks, which are destined to enter passively
into the stomach of a herbivore, and thence to migrate through the body of the latter, either actively, or by the intervention of the vessels, actively — passively.
(The asexual propagation of the brood in the Cestode is rendered improbable even by the fact that, in the
whole development of each of these Cestodea, a sexually mature animal has never been met with.)

Cyst. The resting scolex (cortex), produced by asexual
Generation in and by the large six-hooked embryo, still
concealed within this embryonal vesicle, or lying beside
it enclosed in peculiar cysts, or in closed acorn cavities.
In its non-gnemiparous part the embryonal vesicle ac-
quires, according to the species of cestoid worm, and
according to the different hosts (cold or warm-blooded),
sometimes the form of a globular vesicle, sometimes that
of a flat round, sometimes that of a fist, and sometimes it is only just
sufficient to cover the scolex, lying quite close upon it, when it
really forms nothing but a receptaculum capsae. Thus
we distinguish three forms allied to each other in their degree of development: the cestoidal
forms (Fermentus cystici, intimus, Teresome, Cystoscopia, the plathyvermex, similar to Stein's cystic worm of Teremke melitensis and Von Siebold's from Armoni compressus); and the
acorn-like cysts of embryos of Tetraphyllum. Every one of these is a normal form; even the cestoidal forms are neither morbidly degenerate, nor become dropical, nor
atrophied.

† The resting scoleces, transferred into the intestine of an animal, become converted into the scolex passing into activity. The latter is distinguished from the resting
scolex by the extension of the entire body, by the altered position of the adherent apparatus (cysts and hooks), by the attachment in the intestinal canals, and in the cestoidal
and plathyvermex, by the casting off of the larval portion of the embryonal vesicle, and the forma-
tion of a cicatrix on this spot. In the acorniform no-
thing is cast off, nor is there a cicatrix formation.

† The scolece = the tapeworm colony, bud-
ding immediately from the scolex, which has become active by sexual propagation (generation), is more or
less distinctly jointed, and becomes sexually mature post-
eriorly. In these last segments, which are cast off, and
lead an independent existence, are called proglottides (l.) and bear within them the embryos produced by sexual
reproduction (females). — Küchenmeister, Transl. by Dr. C. F. F. T. pp. 59, 94.)

Whether the cestode worms are developed in the intestines of fishes in which they are found, or are conveyed there in one or other of the animals on which these fishes feed, in which they had been converted into scoleces, after the animal had swallowed the eggs of the parasite, is a question, as to the production of Bothrioccephalus latum in man. This worm has been found in the cat, but is extremely rare in all terrestrial animals. The cat has evidently obtained it from the intestines of fishes, which in sea-ports, and on the sea-coasts, are left in large quantities, and are used as manures. It is difficult, notwithstanding, to account for the presence of this animal in man. The ova from the proglottides of this worm may, however, be introduced into the human intestines by means of vegetables, where the intestines of fish have been used as manures, or where they have been conveyed in sewage with the manures. The passage of the embryo into the intestine of another animal, and its conversion in this intestine into an asexual band-like scolex, is much more probable than the development of all the stages in the same intestine, on account of the dissimilarity existing between the embryo and its parent.

56. C. The Physiological relations of Bothriocce-
phalus are chiefly his weaker vital manifestations, and the smaller number and less perfect development of its sucking organs, than those of the Tenia, which explain its easier expulsion from the intestines. The power of imbuing fluids by the bodies of the Bothrioccephali, and all Cestodes, has been proved by Eschricht and others. Transmission takes place in small, pellucid, ocellated drops (sarcod). Whilst the Nematoidea and Echinophyghi swell up by imbition, the Cestodea, owing to an abundant exudation, experience only a slight swelling from imbition. Whole series of segments of the Bothrioccephali pass off spontaneously from the body, but never single segments, as in the Tenia. The duration of the life of the former is not known. More than one or two worms of this genus are rarely found in the same intestine, and their length seldom exceeds twenty feet.

SYNONYMS. — Tenia, Aristotle; Parascaris, Paredes.
WORMS.—SCOLEX OF _TENIA SOLIUM._

A double circular series. The one series does not materially differ from the other. As in all the *Tania*, the points and spines of all the hooks fall in the same circle, or in two circles lying close together, the number and position of the hooks corresponding with the sexes, and varying from 29 to 28. The suckers are oval, somewhat circular, or somewhat oval, and surrounded by a circular collateral branch of the longitudinal canals, by which a sort of vascular net is formed. Close behind the sucking discs, and near the head, the vessels collect in four main branches, which are united quite at the front of the head by a common transverse branch, thicker than they. In the vessels of various *Cestoidae*, *Vircshow*, *Wagenker*, and others, have seen a sort of ciliary epithelium projecting into them, and moving in the fluid. The *caecalcorpuscles* reach about to the middle of the sucking discs. They are few and small on the head. The _sodden neck_, of about 6" in length, exhibits no traces of transverse strie or segmentation. The caecal corpuscles are somewhat more abundant, and also larger than in the head. Behind the neck commences the true jointed body of the *Tania*, in which *Küchenmeister* counted 625 segments in one specimen ten feet two inches in length. The proportionate size of the segments gradually increases posteriorly, or as they depart from the head—in length from 3/16" to 7/16". In this species, as in all *Cestoidae*, contact with water causes the emission of DUBARDIN's sarcodae, in olistigious drops. The _sexual organs_ appear from about the 200th to the 300th segment, and onwards, from the head, in the median line of the *Cestoidae*, at first as a simple brownish-yellow canal, with short lateral off-shoots, towards which two transverse slightly coloured lines (seminal cord and vagina) run from the sides. The alternating *porti genitalis* first appear about the 317th segment, and become distinct in the 350th. The sexual organs are more and more developed from the 350th to the 600th segment, where ovum commences, which become mature from the 650th to the 700th segments. Both male and female organs generally exist in the same segment, and are minute described by *Küchenmeister*. Each. The neck is very short, poor in caecal corpuscles, opaque, and colourless; the body is wrinkled, abounds with caecal corpuscles, and the head is inverted into it as long as the caudal vesicle is alive and uninjured. After the death of the worm the head becomes everted. (See also § 40. at seq.)

63. (b.) The further proof of the identity of _T. solium_ and *Cysticercus cellulose* is derived from the structure of the head of the latter. "This cystic worm, like all others, forms a vesicle the size of a pea or very small bean, with a little white head in its interior, from which the true scolex may be evolved by pressure. This scolex bears a head with four, and sometimes six, sucking discs (the latter especially in the human brain), round which the vascular system runs, and collects into two longitudinal canals on each side. The short restellum bears from twenty-two to twenty-eight hooks, placed in a double crown. Besides these, the head exhibits a sparing brownish-yellow, or blackish-brown pigment, and five rows round the stemmeister. Each. The neck is very short, poor in caecal corpuscles, opaque, and colourless; the body is wrinkled, abounds with caecal corpuscles, and the head is inverted into it as long as the caudal vesicle is alive and uninjured. After the death of the worm the head becomes everted. (See also § 40. at seq.)

64. (a.) Proof of the conversion of the six-hooked embryos enclosed in the eggs of *T. solium* into *Cysticercus cellulose*—*Küchenmeister*, in 1851, expressed the opinion that the pig infects itself with *Cysticercus cellulose* when it meets with the eggs and proglutodes of *T. solium* upon the pastures; and in 1853 Van Bemmelen administered *T. solium* to two pigs, and thereby rendered one pig measly. The following year *Küchenmeister* fed three sucking-pigs, on the 7th, 24th, and 26th of June and 2d of July, with segments of tape worms, partly given off spontaneously and partly artificially expelled. On the 13th of July they were again fed with artificially expelled segments. "One of the pigs was killed on the 26th of July, and exhibited young *Cysticerci* corresponding with the days of administration, of which the largest individuals formed vesicles of the size of a hemp-seed, with a central turbidity, etc.
commencement of a head. The second pig was killed on the 9th of August, when thousands of Cysticeroci were found in all parts of the body; the largest individuals were as large as peas, and exhibited a distinct head, whilst the smallest were only a few millimeters in size of Cysticeroci. The third pig, which was killed on the 23rd of August, was uniformly set, throughout all parts of the body, with Cysticeroci of various degrees of growth and development. The largest were almost perfectly developed; others resembled those last described, but were found inside the lumen of a weighed piece of the flesh, and found 135 Cysticeroci cellulose in 41 drachms of it. If we calculate from this quantity the number of Cysticeroci which would have existed in 1 stone, or one-fifth cwt. of the pork, we obtain the great number of 86,000 individuals in this weight. A fourth pig of the same litter, to whom no Tanis had been administered, exhibited no traces of Cysticeroci on dissection."

(KEUNCHENMEISTER, Op. cit. 121, 21.)

65. LEEKART repeated and confirmed the above experiment, and recognized, in the mode in which Cysticeroci cellulose is developed from the embryo of T. solium, exactly the same type as that above described as the type of the formation of the so-called Cysticeroci in general. It may, however, be noted, that this worm acquires the vesicular form, and becomes covered with a vascular net, rather early, and at a time when no trace of the head can be observed. The first appearance of the head commences in Cyst. cellulose soon after the seventh week, at which time the embryo is about 2½ millin. in diameter.

66. (d.) The Scolices of Tania solium, Cysticeroci cellulose, has hitherto been found in the most various muscles; in the muscles of the heart, in the cellular tissue, in the brain, and in the eye of man. In these it acquires various forms and sizes, according to the space afforded for its development. In the ventricles of the brain and eye, its caudal vesicle attains even the size of a walnut, and remarkable forms. The size and form of the Cysticeroci are determined chiefly by excess of nourishment, and by the specific nature and other properties of the tissues in which it occurs. The form is not material, the nature of the worm is the same.

67. (e.) The symptoms it produces differ with its seat or position. It is almost harmless in the subcutaneous cellular tissue. In muscles it often occasions but little inconvenience. In the muscles of the heart, however, it may cause softening and other organic lesions. But its situation in the deeper muscles, even in the muscles of the heart, admits not of diagnosis. The situation of this Cysticeroci in the eye is very important.—c. It has been found between the conjunctiva and the sclerotics, where it is of least serious occurrence, as it may easily be removed by operation, as in cases recorded by HöRNER, EHRLEIN, BAUM, and others.

—b. In the anterior chamber. It was first seen in the living subject by SÖsMERRING and SCHOTT; and described by HÖRNER, at 25. In the vitreous humour by the last-named writer and others.—d. In the retina and under the retina, in very rare cases. In these latter situations this cystic worm has been detected during life chiefly by means of the oculum specularum of Halmont. In most of these cases, partial or complete loss of sight by the affected eye, squinting, movements of the worm, inflammation of the structures, followed by partial disorganisation, and a greenish tint of the vitreous humour, were the symptoms chiefly observed. In rare instances only were tape worms present, or Cysticeroci present in other parts of the body. —e. Cysticeroci cellulose in the human brain seldom occurs, and as seldom can be recognised during life, unless, conjoined with cerebral symptoms, vertigo, &c.—f. Cysticeroci are observed in other parts of the body, or Tania solium has been supposed to exist at an earlier period of the life of the patient.

68. ii. TANIS MEDIOfLANELLATA. (KÜECHENMEI TER.)—Description. (a.) The epidermis of the animal is distinct, soft, consisting of delicate dissecting lines, without calcarious corpuscles. Underneath are longitudinal fibres, running through the whole body of the animal; these, as well as the next layer of transverse fibres, contain the calcarious corpuscles embedded in them. The size of the sucking discs, which are quite black, gives the head of this Tania a considerable bulk. Transverse vessels run through the space between the sucking discs, and from these a branch runs to and from the four longitudinal vessels are developed from them in the neck; these vessels becoming thicker as the segments increase in size. The segments, which have a great tendency to increase in breadth, are at first 1 millin. in length, and about three in breadth. Afterwards, also, the breadth predominates over the length for a considerable space. But this proportion does not continue downwards, and segments of 1–1½ in. in length, and only 3–4 lines in breadth are met with. That the last segments or proglottides have a tendency to pass away without faces is beyond a doubt; but this also takes place with T. solium, although more rarely. The segments usually pass when the patient is standing, and passing along the thighs, occasion a moist and cool sensation, and are found creeping over the surface.

69. (d.) This Tanis, when artificially expelled, breaks off close to the neck. After the lapse of about ten weeks, the proglottides and proglottides of segments that have passed, which pass the passage of proglottides takes place. From the spontaneous passage of these faces it may be inferred that the reproduction and growth of the segments are extremely rapid, and that the animal must be more injurious to its host than T. solium.
WORMS—SYMPTOMS AND PROGNOSIS OF CESTODEA.

KÜCHENMEISTER mentions a case in which the number of proglottides, which passed almost daily, amounted, in the aggregate, to upwards of 100 feet in 80 days; and that in the course of this time 1 foot of tape worm was passed and regenerated each day. The internal irritation of the alimentary canal, which is followed by these segments, becomes so great when forcing their passage, and the unpleasant clamminess they occasion, especially by the deposition of their eggs, which often also occurs at this time, and which appear like to a white moist sand, are very distressing to the patient. In the case just referred to, from 6—15 proglottides passed daily from the patient with the faces; and as these immediately laid their eggs, the faces looked as if sprinkled with white sand.

70. (c.) The Scolex is unknown. In Dresden it cannot be rare, as this Tenia is not uncommon there. It is not improbable that the cystic worm belonging to this species may occasionally occur amongst the specimens pronounced to be Cysticercus cellulose. This point might have been determined by feeding pigs with the eggs of this Tenia. An intelligent patient, from whom KÜCHENMEISTER expelled this Tenia by means of his preparation of the extract of pomegranate seeds, states that he had observed his tenia seized after dining frequently, at an eating house, on raw beef steaks and green salad and radishes. The scolex was either seated in the beef, or in mollusca in the salad or on the radishes. "The embryos resemble in size and structure those of T. solium. Their migrations are unknown." Its habitat appears to be in Europe and Africa.

71. VARIETY* from the Cape of Good Hope.

—A number of segments of this Tenia were expelled by pomegranate bark, and like T. medio- cancelata were very difficult of expulsion. They were destitute of head and neck. Its total length must be at least 6—10 yards. Its segments are very thick, white, and fat; in the mature state more than one inch in length, and 3—5" in breadth, and extremely massive. They are distinguished by having a longitudinal ridge along the whole of the mature and immature segments. The scolex, which sent the segments to KÜCHENMEISTER, states that the migrations of the six-hooked embryos and the scolices are unknown, that it is impossible that the latter should live in the flesh of pigs, as the worm was obtained from a hotentot, and the hotentots, like the Jews and Mohammedans, eat no pork. A thick Tenia occurs in Abyssinia, among Mohammedians inhabitants. The hotentots probably brought this tape worm with them from the Caffre wars, in which they enjoyed themselves amongst the cattle of the Caffres. The scolex probably lives in the cattle and sheep. May not the scolex have been a Cysticercus tenuicollis?

72. III. Tenia nana (BILHARZ; VON STEIN 1835).

1 "Corpus filiforme, depressum; Caput acetos obtu- sum, colutum versus extremis atrocinere, acuminata sub- globosa, rostrilo pyriformi uncumulatum ferrulorum corvum hornaturn. Articulis transversis; eirei unsinuantes, ovula

globosa; secta labis simplex; (? insectoria 1/16 magna. Longitudine totum 6—10". Patina scrobiculata. In intestino tenue solum recepta numero permagno."—KÜCHENMEISTER.
munication in either of these directions, or after wounds penetrating into the bowels. These several ways by which segments of tape worm were passed externally were known to the older writers, and were ascribed by them to the mechanical or perforating action of the worm. But it is singular, that, whenever ulceration and perforation of the bowels occur coincidently with the presence of worms, an instinctive desire of the latter to escape from the bowel, through either the morbid opening or the natural passages, is observed.

74. Immature 

T.eius found in the human body externally to, but not within, the intestines. — These form the Cystici and Acephalocystides of older writers. The Cysticercus cellulose, being identical with Tania sili- lum, has been noticed when treating of that tape worm (§ 62, et seq.). I shall only briefly notice the other Immature Tania occasionally found in the human body externally to the intestines.

75. A. Cysticercus tenuicollis (ESCHIRICH), Cysticercus vesceralis (AUD.) — As the mature Tania, of this cystic worm is not found in man, but chiefly in the dog and wolf (Tania marginata), I shall not attempt to describe it here. It is not a form of common occurrence, as the writer is not aware of it having been described by any observer.

76. (a). The Scolex or immature state of this Tania, being sometimes formed in man, especially in former times, requires a brief notice at this place; it forms the Cysticercus tenuicollis of recent writers, and the C. vesceralis hominis of earlier authors. The rarity of this scolex in human subjects in modern times has induced Vic- chow and Diezing to doubt its occurrence, whilst Eshirich has proved its rare appearance in man, especially in the liver.

77. (b). The structure of this Cystic worm is rendered remarkable by its frequently enormous caudal vesicle, which in animals may attain the size of a child's head, by the concentric wrinkles or rings, visible externally, which pass round the worm, and which are crossed by very fine longitudinal striations, appearing as a net, when viewed upon a plate, and held on the same plane with the eye, the animal has a finely chequered appearance. In the dead Cysticercus tenuicollis, incrusted with calcareous matter, these concentric rings may be recognised, and the calcareous deposit often forms a plaster-like coat of the form and structure of the cystic worm.

78. B. Echinococcus.— Some naturalists admit only of one species or variety of Echinococcus, others of two, and others of even a greater number. Von Stehfeld divides this species into E. hominis and E. veterinarianum; but, from the accounts of various writers, both varieties have been found in the human subject.

79. 1st Var. Echinococcus solliciparius* — Echinococcus veterinarianum, of authors.

Sym.-—Tania vivescralis granulosa, GÖE; T. granulosa, Gmelin; Vesticaria granulosa, SCHRANKE; Hydatis erratica, Blumenbach; Polycephalus hominis, GÖE; Pol. granulosa, ZEDER; Pol. Echinococcus, ZEDER; Echinococcus veterinarianum, RUDOLPH; Echin. giraffe, GERVAIS; Echin. simiae, RUDOLPH, allique; Echin. granu- loss, RUDOLPH; Echin. infaustus, LIEBIG; Echin. polymorphous, DIEZING; Echin. solliciparius, KÜCHENMEISTER.

80. (a). The mature Tania has hitherto not been found in the human subject. Von Stehfeld in 1852, and KÜCHENMEISTER in 1854, bred this Tania by giving Echinococi to dogs. The description in the subjoined definition gives all the characteristics supposed to be known of it; but the eggs and six-hooked embryos must occur at some period in the human intestines, in the water and raw articles of diet, especially vegetables, fruits, roots, &c. Like the embryos of other Tania, however, they escape the human eye of my limited space is describing it, and the writer is not aware of them having been described by any observer. They take up their position in the same way as the other Cysticercus, the envelopes formed around them being similar, but much thicker.

81. (b). The Scolex forms a vesicle which, according to Eschirich, measures 2½—3 inches, and is firmly attached to the organ in which it develops. The enveloping cyst is like others, but more concealed, and more abundantly perforated by proteinous un-organised substances, by which its walls are thickened. It may be partly separated into layers, the inner being smooth, like a serous surface. A second vesicular body lies exactly to the inner surface of the true cystic worm, that is, to the outer surface of the Echinococi, that is, the six-hooked embryo, which, continually increasing, has attained an extraordinary size. It is almost impossible to get the cystic worm uninjured out of its cyst, to which it adheres with great tenacity. —

* Tania matura.—Tania vivescralis, ad 3 mill. long., corpore 3-4-articulato. Capitum subgloboso, 0,3 mill. long., rotellato. Parvo 0,125 mill. long.; ovula e corpori ovuli nullius 0,13 mill.; hamuli in duplo ordine positus 28—30; quorum unus secus ille Leucorastis numera 0,094, numerus 0,083, ex eos mensuram ex 0,066 habent. Collo longissimo. Articulis 3—4, quorum ultimus duo corpus longior (3 mill. long.; 0,5 mill. int.) ubi utero medio localis et subalabrum nec tannis propriis structur.; Ovula calibrum, 0,034 long. et 0,038 lat.; nucce 0,015 mill. crassus, cavitate interna 0,027 lat. et 0,050 long.

Habitat. In Canis domesticis, inprimis in Canis levis, fortasse etiam in Canis lupi, tubo intestinali.

Scolex (fig. 3).—Echinococcus solliciparius. Fr. vicus minus peltudous, membranaceus, ex partibus ad 1—1 mill. crassus, ex pluribus 0,005—0,01 mill. crassitudinem concentricis, parvis globulis (brood-capsules) stipitibus pigmentis quibus sollicarius singulis praebetur, magnitudine in 30 mill. et ultra eruditus. Sollic- ius sollicia sollicis, metameribus, in levis corpore, parvis Tania modo dice. Metamerophora in Taniao post 7—8 hebdomadum peracta.
WORMS.—DESCRIPTION OF ECHINOCCUS.

The walls of this worm are elastic, and tremble like jelly, when touched, even after they are empty. They never collapse altogether as seen in _Cysticeri_, nor lie, like these, even when dead, at the bottom of the envelope-cyst. Their cut margins roll themselves up, and present a gaping appearance. The transverse section of this organ worm shows a structure of more or less numerous consecutive circular strata, varying according to age.

82. c. The structure of this cestode has been described by Eschricht, von Sterbold, and others, who say that its parietes consist of two similar membranes, loosely connected, the outer being firm and cartilaginous, and the inner thin and smooth, resembling a mucous surface, which is beset with small elevations of a size up to \(\frac{1}{4}\)", which are partly very young scolices, in the act of development, partly further developed scolices of \(\frac{1}{4}\), and partly the points on which such scolices formerly sat. In the fluid contained in these vesicles there are also free scolices, part of which are still furnished with the remains of the stalk. For other minutiae of structure I must refer the reader to Dr. Lannester’s translation of Kuchenmeister’s work.

83. This cestode worm is found chiefly in the livers of man and of ruminating animals. It has been detected also between the choroid coat and the retina of the human subject. When present in the liver, this organ is generally swollen, especially posteriorly, pale, or of a uniform greyish-brown colour. Its surface presents larger or smaller spots of a whitish-yellow colour, of a regular form, and very slightly raised. This species is generally seated so deeply as hardly to project above the level of the surface of the organ, unless it is very largely developed.

84. a. The symptoms caused by this Echinococcus are usually slight, limited, and equivocal. The vesicles seldom exceed the size of a walnut or hen’s egg. Even when they are present in numbers, their diagnosis is most difficult. When they are small or few, the disturbance of the functions of the liver may be slight. When more numerous or more fully developed, there are generally pain and uneasiness in the hepatic region, with increased pulse and temperature, and sometimes the dull sound on percussion being more extensively heard, and the liver being often felt from one to two inches below the false ribs. There is also irregularity of the bowels, the evacuations being unhealthy, and often deficient in bile. Jaundice is sometimes observed. But all these symptoms may be caused by other lesions of the liver.

86. Kuchenmeister* believes that this species has been confused with the preceding.—a. Its mature _Tenia_ is unknown. Nevertheless, he thinks that it probably occurs in the human intestines, and indeed in the intestines of those individuals who suffer, or have suffered, from the species of Echinococcus belonging to it in some part of their bodies, and in whom such a colony of Echinococcus has opened towards the intestine. This species also develop itself in the intestines of domestic carnivorous animals. That the eggs and embryos must occur at some time or other in the human body must be admitted, although they escape observation from their small size.

87. b. The _Scoleces_—the Echinococcus alveolaris—occurs not only in man, but also in the larger domestic animals, especially Herbivora. It is very prevalent in Iceland. Dr. Schleisner states that he saw fifty-seven human patients suffering from Echinococcus in that island; that it occurred more frequently inland than on the coast; and that it constituted one-eighth of the diseases of the intestines. Dr. Thorstenson of that island says, that every seventieth living human being in it suffers from Echinococcus; that females are more liable to them than males, and that their abundance increases with age, men being most frequently attacked by them between the third and the fourtieth, and women between their fortieth and fiftieth years.

88. c. The characteristics of this species of Echinococcus, as distinguished from the preceding, appear to be as follows:—(a.) The enveloping cyst, and the mode of annexation of the inner wall of this cyst to the primary vesicle of the _Echinococcus_ derived from the six-hooked embryo, are similar in this and the foregoing species; but the cyst, formed by _Echin. alveolaris_ is much larger than that of _Echin. scoliciarius_, and hence projects far above the level of the organ in which the colony exists.—(b.) Owing to its much greater bulk, a proportionately increased interference with the functions of the organ results, and eventually with the whole organism.—(c.) As regards the animal itself, we find not only single scolices or a single vesicle in such a colony, but the constant production of fresh vesicles with young (daughter- and grand-daughter-vesicles), sometimes with, and sometimes without the darts surrounding the darts of the scolices, or interferring directly to the walls of the vesicle. According to Thorstenson and Schleisner, the hydatids occurring in Iceland exhibit this structure. “The hydatid sacs,” they state, “are formed not only in the human liver, but also in many parts of the abdomen, and are often of enormous size. Hundreds of hydatids are frequently evacuated through the external opening of the sac, or with the stools, and in vomiting. They do not, however, occur only in the interior of the body, but also very frequently in the skin, where they appear like large saccular swellings. The course of the disease is very chronic.” Kuchenmeister states that the vesicles produced do not, like the original mother-vesicle, bear six embryonal hooklets, as they never have occasion for them. The six hooklets may be sought for in vain, even in the mother-vesicle, as, although certainly present, they must, from their extreme minuteness, escape detection on such a large scale.
vesicle. The smallest of the granddaughter-vesicles are but just visible, and enclose four, five, or more scolices, which adhere peripherally, by a small stalk, to the inner wall of the common cyst, but converge with thin free ends towards the centre of the cavity of the small vesicle. In very large daughter-vesicles scolices also swim about freely. — (d.) The scolices produced or nursed by the mother-, daughter-, or granddaughter-vesicles, are in general more slender than those of the preceding species: they have the head with the double cirecle of hooks, more frequently protruded during life, at least within the larger daughter-vesicles, exhibit distinctly marked sucking-discs, and bear a greater number (46—54) of hooks, which appear more slender than in the preceding species. — (e.) The dwelling places of this species are not limited. They may occur in the liver, the lungs, the kidneys, the sheaths of the testicles, the spleen, the ovaries, the breasts, the throat, in the sub-cutaneous tissues, in the bones, &c. — (f.) With the increase of the secondary and tertiary cysts in the mother-cyst, the swelling advances; and the more rapidly this takes place, the recognition of the malady and its natural cure are facilitated; inasmuch as the mother-cyst is often burst by the distension, and probably in many cases becomes destroyed. Sometimes, however, the burst colony appears to heal and to recommence the production of fresh daughter-vesicles.

93. The prognosis of this species is more unfavourable than that of the preceding, although the diagnosis is easier, on account of the more rapid growth and greater bulk of the swelling, the occurrence of the hydatid-buzzing, and the more distinct sensation of fluctuation. The structure of the walls of the mother-vesicle is the same in both species, and is characterised by the numerous parallel concentric layers in the substance of the walls, which appear more distinctly marked in the daughter-vesicles, and make their appearance with remarkable clearness after treatment with caustic potash, with the addition of a drop of red ink. — (Lankester's Trans. of Kühneimester, &c.)

94. v. The Diagnosis of Echinococcus.—The symptoms produced by a colony of these parasites is very similar to that of the former, and with the size and pressure of the tumour it develops. At an early stage of their growth these animals generally occasion little inconvenience, and when largely increased in bulk, they produce phenomena which vary little from those occasioned by tumours of the same size, in similar situations. Their superficial or deep-seated positions, and their vicinity to, and pressure upon, nerves and blood-vessels, will also modify effects, or even indicate their existence. But it is comparatively rare to obtain certain evidence of the presence of a colony of Echinoccus in the body, unless the passage of the gelatinous vesicles already described from the cavities after the bursting of such a colony, or from the punctures or incisions made into tumours. At the same time, the little scolices of the Echinococcus must be found in the vesicles, part of these retaining, others wanting their hooks, their sucking-discs being often indistinct. From the vesicles passed have been obtained, the little scolices slip out very easily, and if the structures just mentioned be not found, it is doubtful whether or no a sterile colony or an acphaloxyct is present.

91. Before perforation or bursting of the cyst has occurred, the tumour produced by it being very considerable, an examination of it should be made by palpation and percussion, and if there be an obscure or sensitive fluctuation, and when anaemic symptoms are wanting, and when the general health is either good, or not injured to the extent that might be expected from the size of the tumour, and if it were of a malignant nature, then an explorative puncture should be made to complete the diagnosis, and the evacuated fluid examined by the microscope in order to ascertain the presence of Echinococcus scolices, or of albuminous gelatinous shreds of Echinococcus. By these means only can the nature of a cystic or calcified, fluctuating or elastic tumour be determined, and the existence of the parasites ascertained. —

92. Without these proofs the diagnosis can never be brought beyond one of probability. A calcified or cystic swelling filled with fluid can alone be inferred. The fully developed typical symptoms are the existence of such a tumour, which is elastic to the touch, and of a peculiar consistency.
and form, in places where swellings do not usually occur; but, when those do make their appearance, they are generally of a considerable size; a moderate degree of probability that an unopened tumour belongs to a colony of *Echinococci* is attained when the swelling occurs in places such as the liver, spleen, kidneys, lungs, breast, testicles, throat, etc., where *Echinococci* are otherwise brought to light, either artificially or naturally. On percussion, the finger, placed over the swelling, often feels a tremblingly dense and, on osculation of the mass underneath it, especially when several gelatinous tremulous cysts are included within a larger vesicle; these being set in motion by the percussion appear to produce this trembling or oscillation, which however frequently is not felt. 93. §. *The Etiology of the Echinococci* is manifestly the ingestion of one or more of the eggs or six-hooked embryos of the *Tanis Echinococcus alveicuparius*, at some time of the life of the patient. The mode of life of persons in some localities, and in some circumstances, may be favourable to the passage of the eggs of this *Tanis* into the stomach; and the food and mode of life of the patient often have a very limited habitat. "The duration of the life of the *Echinococci* does not appear to be very short. According to Escholtz, one patient must have borne his colony eighteen years."

94. g. *The Prognosis of the Echinococci varies* according to the organ in which they are seated, to their situation in that organ, and to the primary and consequent injuries caused by them to the organism and to the whole system. But the prognosis is upon the whole more favourable than is generally supposed, especially when the general health and the powers of vital activity are duly promoted. "The tumours, when they are accessible, are amongst the number of curable tumours; they may cure themselves by bursting, and when they are once got rid of, relapses in the same colony are rare and exceptional cases, and every *Echinococcus* produced usually owes its existence to a new immigration of embryos. But for this very reason the continuance of the mode of life in endemically affected places furnishes a more favourable prognosis. The natural cure of the bursting of the colony, and the passage of daughter-vesicles may be accompanied by symptoms dangerous to life, or if it take place in the direction of the larger branches, by difficulty of breathing; or may even lead to actual suffocation." (Op. cit., pp. 227, 228.)

95. B. Sub-order, Trematodidea.—SYNON.—Myxymia, Dissing; Egelswermer; Platelmintha volatia, Isolated flatworms, KÜHNEIMSTEINER.

DESCRIPT.—"Animalia solitaria, planumque hermaphroditico, rarsissime specie distincta, et parum planumque sueteris, medians aut lateralibus in structura. Canalis eisarii furoris dicavi aut ramosus, rarissime simplex. Evolution fuit planumque metamorphosi et suspensione generatione alternante, rarissime sine ilia."—LEUCKART.

This sub-order is divided by KÜHNEIMSTEINER into two Families, the Monostoma and the Distoma.

97. (a.) MONOSTOMA.—SYNON. CUELLARIUMS.
corpulation with a second individual." This distoma occasions great devastation in the livers of herbivorous and domestic animals, especially in wet seasons; but it very rarely occurs in man.

99. b. Diagnosis. — Distoma in the liver causes dilatation and inflammation of the gall-duets, and distension of the bile due to large vesicles of large portions of the parenchyma of the liver in the vicinity of the enlarged ducts. These changes, however, cannot always be recognised, or referred to their true source in the human subject, as several lesions of the biliary organs and apparatus occasion the same symptoms as they produce. The distoma may even cause many of the phenomena of gall-stones passing along the ducts, with or without more or less jaundice; but these cannot assist in establishing a diagnosis, the passage only of the animals with the feces or with the matters vomited being the only proof of their presence in the human subject.

100. c. It is obvious that no prognosis of the Distoma malady can be formed unless the animal be discharged and recognised. When this takes place, although the prognosis is upon the whole un- favourable, yet there may not be any immediate danger. The life of the patient may be prolonged or even a recovery ultimately be effected by providing for the secretions and excretions by suitable means, and by supporting vital force and resistance.

101. d. Distoma lanceolatum * (MEHLIS). — This species was seen in the human subject by BECHTLER, CHABERT, and MEHLIS. It is narrow and elongated, and distinguished by its long neck, through the want of any spinous coat, and by the female organs especially occupying the abdomen, and the testicles the anterior part of the body. SCHAEFFER, RUDELFIH, and MEHLIS established this as a distinct species of Distoma, and showed that GOETZ, ZERER, BRESER, were wrong in regard to it as a young Distoma hepaticum. It is stated by KICHEIMSTEINER to be less injurious to the structure of the biliary apparatus than the D. hepaticum. The prognosis is possible only when it passes off. The prognosis is probably more favourable than in the case of the other parasites.

104. b. In the intestines are found deposits upon and beneath the mucous membrane, verrucose

and lobate fungous excrescences, and also the aggregations of the eggs in the vessels of this membrane, "where the eggs are often fixed in rows in the mucous and sub-mucous tissues, in and beneath the croupous exudations upon the intestinal ulcers; and, lastly, after the rupture of the vessels upon the free surface of the mucous membrane."

105. c. Distoma on the liver. — "The entire trunk of the portal vein is sometimes filled with mature animals, with eggs in the substance of the liver; and it is not impossible that the Distomas situated in these places may give rise to a tough, dry, anaemic consistence of the liver, or perhaps even to abscesses."

106. d. The alterations in the urinary bladder produced by Distoma hematothobium are at first circumscribed spots of hypervenemia, with bloody extravasation and swelling of the mucous membrane, or tenacious mucus, with greyish-yellow masses of exudation, in which the eggs are imbedded. It is rare that the whole interior of the bladder is injected and ecyemized. The urine is mucous, but pale and clear; and Billharz found eggs in the urine passed. "In later stages, yellowish discoloured elevations, mixed with many pigment spots. These elevations often form a soft coat, sometimes a line in thickness, mixed with bloody extravasations, firmly attached to the mucous membrane. Sometimes calcareous incrustations of the egg-shells, the deposition of the salts of the urine, and the aggregation of eggs, give the whole a sandy texture. Very rarely this coating covers true ulcers with loss of substance. At other times, single or aggregated vegetations, varying from the size of a pea to that of a bean, of a yellowish colour or ecchymosed with blood, are found on the vesicle mucous surface. In the smooth-edged spaces of these vegetations, sitting in the sub-mucous tissue, formed by the diverticula of its vessels, and only constituting productions of the vessels, Billharz first found the Distomas, and in the mucus and exudation over these spots their eggs. We may conclude from this that the Distoma collect there, and in similar situations, to lay the eggs which are to be passed off.

107. e. The mucous membrane of the ureters, either alone or with that of the bladder, or even with that of the pelvis of the bladder, is attacked in a similar manner. A gravelly matter, in molecular masses of imbedded eggs of Distomas, or sometimes empty or containing embryos, with blood, exudation corpuscles, and crystals of uric acid, is sometimes passed in the urine. Individual embryos also occur free, but Greenshores found these in a dead state only. In consequence of the thickening of the inner coats of the ureters, complete or partial occlusion of these ducts with dilatations above it, with retention of urine and its consequences, sometimes supervene. The kidneys are somewhat swollen and congested with blood, and the mucous membrane of the pelvis is much injected. The kidneys, in rare instances, ultimately degenerate in a fatty or sucty state. "The aggregation of eggs of the Distoma are not frequently the nuclei of deposits of gravel and stones, consisting chiefly of crystals of uric acid, in the kidneys, ureters and bladder, and thus give rise to the well-known consequences of stone and gravel.

This is the Lithiasis of the Egyptians, described by Prosper Alpinus in "Medicina Aegyptiorum."

108. The seasons appear to have some influence upon the frequent occurrence of this worm, as it has been observed to be more abundant from June to August, and more rare in September, October, and January. This difference is probably owing more to the kind and quality of the food in these months, than to temperature or season.

109. f. The symptoms of this parasite are manifested chiefly in the urinary apparatus, and in the urine itself, at an early period of the lesions produced by it. Causeless hematuria, especially if frequent, and attended by anemia, emaciation, and disordered bowels, should be a cause of suspicion, especially in tropical countries. The diagnosis, however, during life, can be certain only when the eggs are found in the bloody urine and in other evacuations, as they were by Billharz.

110. a. Distoma ophthalmothobium * (Dessing). — This parasite is found in the eye of an infant, between the lens and the capsule, by Gescheidt. The infant was five months old, and was born with cataracta lenticularis, with partial suffusion of the capsule. Four specimens of this Distoma were found, and were recognisable by the naked eye.

9. Order, Nematomia — Nematodea. — Thread-worms, Round-worms. At present known to be the First Order of Rudolfi. — "Nematodea: Corpus elongato, tereti, elastico." Dessing, in his "Systema," arranges them as the Sixth Order of his first sub-class, and defines them as "Nematodea: Corpus elastico, ovato, subequantim curlus; tractus ciliarius simplex; corpin in proboscideum hand protractile. Endoparasita, tandem varias exstis libere vagantin." They form the second order of Kichenmeister's second sub-class, and he defines them as follows: — "Nematoma: Corpus teres, elastico, serpentinum, filiforme; ovum centrali, vel sub-centrali; canalis ciliarius ant distinctus ant obvelo, quoque destititus. Metemorphosis in capsulae, Migrationes activae aut passivae in permutis."

112. Mature Nematode Worms are met with in the human subject in the cavities of the body, having mucous or sub-mucous surface, in the subcutaneous cellular tissue, with an artificial external communication, and during their youth, and in an immature state, in various muscles, especially primitive muscular fascia. The division of this order of worms into numerous genera and species has been attempted by Dujardin, Von Siebold, Dessing, and others, but without sufficient agreement to admit of further reference to it than is made by Kichenmeister, who does not adhere to a strict classification, but rather reviews them in accordance with their dwelling place in the human body, and selects for them the name, as generally employed. It was formerly thought that the Nematoidea were the most accurately known of Entozoa; but at the present day we have more positive knowledge of the history and development of the Ceptode Worms, and even of the Trematoda, than of this, the order of Round worms.

113. "The distinct presence of a digestive
apparatus, divisible into mouth, oesophagus, stomach, intestine, and anus, the separation of the sexes into two individuals, the certain detection of a nervous system in some of them, and the apparently jointed structure of the round worms, being the more certain. In the human subject we must take into consideration the Trichoeophalii and Trichinæ, 2, the Oxyur, 3, the Strongylidæ and Ascylctostoma, 4, the Filarias, 5, and the Ascaridæ. (Op. cit. p. 269.)

114. A great part of the Nematode worms appear to reach maturity only after they have undergone various immigrations and emigrations during their youth. One species of round worm common to man is to such extent capable of migration also in the mature state. The migration in the early stage of development consists of the escape outwards of the eggs of these worms with the human faces, with which they get into dung-hills, sewers, &c., and experience the transitions described above (§ 7, et seq.). My limits admit not of an account of the sexual and other organs of this order of worms, and of the various stages of their development; sufficient reference to these topics for practical purposes has already been made to, and the reader may refer to the more minute descriptions of Küchenmeister and von Siebold, and of other recent observers, to whom I have referred.

1. TRICHOEPAHUS, * syn. Trichuris, Roederer; Ascaris, Linstaus; Mastigodes, Zeder; Trichoeophalus, Goeze, Diising, Dujardine, &c.

115. 1st. Trichoeophalus dispar, with its proper gynaæ as Trichina spiralis, Owen and Luschka.

SYNON. Triehoeophalus dispar, Goeze. Tri-

churis, Roederer and Wagner; Ascaris, Linstaus; Mastigodes, Zeder; Trichoeophalus, Goeze, Diising, Dujardine, &c.

116. A. This worm was first discovered by Moraschi in the caecum and vermiform appendage of typhoid patients; and Romberg and Wagner, in 1761, recognized it as a distinct worm, in the "morbus mucosus," or mucous fever, so prevalent in Germany in the middle of the eighteenth century. It was long supposed to exist only in the intestines of typhoid patients, but it is now fully ascertained to have no particular relation to any disorder of the human bowels. It is found chiefly or only in the lowest region of the small intestine, near the ileo-cacacval valve, in the caecum, and colon. From the dingy colour of the worm, it is liable to escape detection, and only is detected with ease when the lower intestines are free from their thick and coloured contents, as in disorders attended by diarrhoea. If carefully sought after, these worms will be found more frequently and in greater numbers than is commonly believed. Rudolph found many hundreds in the situations just named. Bellingham saw upwards of 100 in the caecum only of one patient in Dublin. They occur in the male and the both children and the elderly persons in Europe and Africa. Küchenmeister's work is still in translation by Dr. Lankester, and contains many minute descriptions of the organization of this parasite. The subjoined systematic description is sufficient for all practical purposes.

117. B. Trichina spiralis (Owen and Luschka), as the brand of Trichoeophalus paras, is engaged in migration. This asexual worm was first described by Owen in 1835, although previously seen by Tiedemann in 1822, and by Hutton and Wormald in 1833. It was afterwards seen and described by Page, Knox, and others. The seat of this worm is, as well known, the muscles of voluntary motion, and indeed all the muscles excepting the heart and the sphencter ani, where it has not yet been found. In the places where capsules of Trichina are eaten, fatty tissue is constantly inserted, chiefly at their anterior and posterior extremities; the fat being apparently deposited to fill up the space produced by the Trichina having penetrated between the muscular fibres.

118. A. The development of Trichina spiralis seems to be as follows:—When a human being
has swallowed the eggs, or the youngest brood developed into ready-formed embryos which occur in the eggs, or perhaps also when any female Trichoecephali residing in the small intestine scatter their eggs with the ready-formed embryos in them, and when in either case the egg-shells are burst, and the embryos set free in the intestinal canal, the desire of migration awakens in them, and they set out, like the embryos of many other Nematoda, in the shortest and easiest way towards the tissues which they prefer as their resting place. That in this case, as in that of the Cestoda, the digestive canal may be the place of immigration from the exterior, is shown by the fact that the muscles of the tongue, pharynx, and oesophagus, as well as the sphincter ani internus, are visited by the Trichinae. In some cases the blood may be the bearer of the migrating brood. Münzner found the young attached to the inner walls of blood-vessels, and of the heart; and both he and Leuckart think that, the circumstance of the brood of cestode worms being found so abundantly in the blood-vessels, shows that the blood is their most usual course of migration. Kuchenmeister believes that both courses of migration are followed by penetrating the tissues, and by the blood. The Trichinae having found a resting-place, a cyst closely adhering to the tissues is formed around it. This cyst consists of concentric layers of a fibrous or lamellar substance, with imbedded cell-nuclei. The brood reposing in this cyst approximates the head and caudal extremities in spiral turns, without, however, contracting a part of the head, and is then perhaps surrounded, even on the part of the worm, with a peculiar layer, but certainly enveloped on the part of the host, with a capsule and cyst, in which the worm increases in size; and, besides the intestinal canal, develops the primitive foundations of an organ which belongs to the generative apparatus. The material for the capsule or cyst enveloping the Trichinae, according to Luschka, is formed from the inflammatory exudation produced by the passage and site of the worm; and hence the cyst varies in appearance with the time which has elapsed since the immigration, the oldest cysts exhibiting a more or less dense pellicle, without any organic substance, this deposition of lime-salts increasing with the age of the cyst. Sanders and Kirk state that there are around the worm 1, an external fibrous envelope; 2, a tolerably thick layer of a white, transparent, homogeneous substance; and 3, an internal round capsule.

118. b. The contents of the cyst consist of one or more animals, and a small quantity of fluid, which keeps the inner envelope extended (which envelope Kuchenmeister and Luschka believe to be derived from the animal itself); the fluid is sometimes clear, especially in the comparatively young Trichinae. In cysts with worms recently dead or destroyed, it showed traces of organic decomposition. In cysts with worms which have been long dead, or in those which contained no worms, which are rare, is found a clear, thickish fluid, with small formative elements, or only a few elementary granules. These wormless cysts probably had previously enclosed a Trichina, which had died, and that a complete solution of the worm had taken place, or which had migrated from the cyst, and wandered to some other situation, where it had again become encysted.

120. As to the destination of the Trichinae, there is no doubt that a great number, if not all, of those which occur in the muscles of man, become abortive and die. The latter then lie in their cysts, in the midst of the cyst-fluid, which is in course of sclerosisification, desiccation, and calcification, rolled in spiral convolutions, in the same way as the Trichina seen in a living state. These spiral structures are, however, broken up into fragments, which indicate a ringed appearance or a segmentation of the bodies of these animals, but how these encysted nematode worms, with our present state of civilization, can reach, before the period of their death—which, however, only occurs very late, perhaps in 30 to 40 years, or after a still longer period in particular cases—places in which they are in a position to pass through their further and higher development, is beyond my power to divine (Kuchenmeister). On this subject, the experiments of this writer, and of Zncker and Leuckart, have thrown no light.

121. c. The reasons which have induced Kuchenmeister to regard the Trichina of Owen and Luschka as the young brood of Trichocephalus dispar, and to consider both these nematode worms, hitherto placed separately to the blooding one species, are the following:—1. The skin of both has a peculiar ringed and jointed structure, which presents itself more distinctly than in many other Nematoda. 2. In both, a longitudinal stria runs down the sides, indicating the limit to which the contractile parenchyma of the worm, in which its internal organs are imbedded, reaches. These striae are certainly the points of attachment of the parenchyma to the inner wall of the integument of the Trichina. 3. The alimentary canal is organised in exactly the same way in both. The mouth and anus are situated exactly in the centre of the two extremities of these bodies, the anterior and posterior; this circumstance excluding the Ascarides, Oxyurides, and Strongylida, and most of the Filariae, from any relationship with Trichina spiralis. 4. The second tube which occurs in the abdomen, together with the intestinal canal, favours the identity of the two worms; the course of this tube admirably conformed with the exigencies of life, to produce either female or male Trichocephalus. For these reasons Kuchenmeister regards the Trichina as the brood of Trichocephalus engaged in migration, by swallowing which we infect ourselves with the Trichocephalus dispar of both sexes. The symptoms produced by these worms have not been observed or stated. Even the immigration of the brood of Trichina appears to take place without any general reaction, and is also borne without injury for many years.

122. ii. Oxyurus==sharp-tail (from ὁξυς and οἶπος). This name applies only to the female, but by no means to the male. This worm is differently classed by Dujardin and Diesing, whose classifications are too artificial, and too subdivided to admit of notice at this place. The Oxyurus, according to Dujardin and most other authors, is a genus of Nematoda separated from Ascaris. This writer gives the subjoined systematic description of it.
123. Oxyuria vernicularis, Bremser, Du-Jardin, von Siebold, Goetz, Rudolph, Diersing, &c.; Fasuria verniculata, Zeder; Kinder-, Mastdarm-, Madenwurm; Thread-worm.* — a. Three forms as to site, sex, &c., of these worms are met with. 1. The mature females, which are remarkable for their size, thickness, and whiteness, for their acute capillary tail, and for an obtuse, broad head. 2. The young immature females resemble the pale-gray colour of the males, but they are somewhat larger than they, and are recognized by their acute tails, and by the female sexual organs in grades of development varying with their age. 3. The mature males are remarkable by their pale silver-gray colour, and their obtuse anterior and posterior extremities, as also by the penis. All the three forms occur abundantly in one and the same intestine. The skin, head, and oesophagus, and intestine are similar in both sexes. The nervous system of the Oxyuria is, according to Walter, greatly developed, although hitherto overlooked. They have both cephalic and caudal ganglia, with other ganglia, plexuses, and lateral filaments, which are minutely described by Walter and Kuchenmeister. The primitive nervous filaments are produced from the processes of the ganglionic cells; by the union of several primitive filaments of this kind, narrower or broader branches are produced. The skin of the oxyurids consists of an external epidermis, and beneath this a delicate but dense fibrous corium. The parenchyma of the body does not extend into the tail. The muscular system is highly developed. The alimentary apparatus consists of a mouth, oesophagus, stomach, intestine, rectum, and anal cleft. For a minute description of these and of the sexual organization, my latest oblige me to refer the reader to the works of the authors just named, who ascertained that the males of the oxyuris vernicularius are much more numerous than was formerly supposed.

124. b. The locality of these worms in the human body is the lower portion of the intestinal canal, especially the rectum. They occasionally stay up-wards, but rarely higher than the lower part of the small intestine. They wander, however, out of the anus and into the vagina of females. Although most frequent in boys and young persons, yet they are not uncommon at all more advanced ages, even in the most aged, in whom I have repeatedly found them the most tormenting. They are gregarious, forming balls in the large intestines, frequently along with other worms, especially the Ascaris lumbricoides. J. P. Frank found them in the intestines of an infant so young that the umbilical portion of the chord had not separated. They are, of all the Helminthia, the most unpleasant tormentors of every age and of every people; for they are not limited to particular parts of the world.

125. c. Symptoms. — These vary with the number of the worms and their position. A few hardly occasion any marked symptoms; but when numerous, in the lower part of the rectum, they occasion extremely distressing itching and an irritating annoyance, difficult to be described, extending to adjoining parts. Certain articles of diet, as onions, carrots, fruits, &c., render the worms more restless and irritating during the whole day; but they are generally most annoying when the patient goes to bed. When the patient falls asleep, grinding of the teeth, excitement of the sexual organs, and restlessness are caused by them. The consequences of this local and constant irritation are, especially, and subsequently to, the period of puberty, increased sexual irritation, masturbations, &c., both in sexes, and in the latter, the most distressingly when the worms wander into the vagina, when they occasion not merely pruritus but also lencorhinuma, &c. The loss of rest and the irritation they produce, ultimately impair nutrition, give rise to pallor, anaemia, and loss of
WORMS. — STRONGYLUS AND ANCYlostomum DEScribed.

120. a. When fresh, this worm has a reddish colour. In spirit this colour fades, and the worm assumes a greyish leaden hue. Four longitudinal stripes are observed on it. The total length of a female specimen was 19 inches. Dujardin states that the vagina opens 1 to 2 inches from the caudal extremity. It has been said that the system of nerves is most manifest in this worm, a remark which is confirmed by Blanchard, Otto, and Von Siebold.

130. b. The symptoms of this worm are equivocal, for there can be no evidence of its existence to be relied upon, until it is discharged, thereby demonstrating its existence. Another species of Strongylus, the S. longisegmentatus of Diesing, has been said to have been found in the human subject, but without sufficient proof.

131. iv. ANCYlostomum. — *Ancylostoma, Dujardin.* — Ancylostoma, Creplin. — This worm was discovered by Dujardin in 1836, in the duodenum, and upper part of the jejunum; and subsequently also by Pruner, Bilhaze, and Griesinger, in the countries watered by the Nile. According to Von Siebold, it has never been found in Europe to the north of the Alps. Dujardin established this as a distinct genus from the Strongylus, by the symmetrical arrangement of the dental apparatus. We are, however, at present acquainted only with a single species of it.

122. A. ANCYlostomum duodenale. — *Bilhaze,* having had his attention called to this worm by Von Siebold, in consequence of Pruner having found it in Egypt, has examined it after death in that country, sometimes in small numbers, sometimes in hundreds, less in the duodenum than in the jejunum, between the transverse folds of the mucous membrane. One male is found to three females. At the oval end, a large, obliquely truncated horny capsule, furnished with four strong teeth on the projecting portion of the upper margin, is seen. The oval orifice is turned to the surface opposite to the sexual and anal orifices. The animal attaches itself by its mouth so firmly to the mucous surface
that the mouth is torn away when it is detached by force. Its nourishment is blood, as proved by its intestine being filled with this fluid.

133. a. Pathology.—This worm is of great importance and is often fatal to those afflicted with it. Griesinger, the best chemical observer of this worm, states that this worm attaches itself firmly by biting into the mucous and submucous membranes; and that the spot on which a worm has been attached is indicated by an ecchymosis of the size of a lentil, in the centre of which, a white spot, the ‘eye’, is always present, which is pierced by a hole penetrating into the submucous tissue. From these wounds the blood enters freely into the intestine of the worm, which is filled with blood from the punctured places. Frequently the mucous membrane of the intestine is studded with flat, live, brownish-red elevations of the size of a lentil. This is owing to the collection of the blood between the mucous membrane and muscular coat. In some cases a specimen of the worm is found lying in the cavity thus formed, covered with blood, with which it has completely engorged itself. The manifest consequence of this is that the circulation in the intestine is impeded; Griesinger imputes the “Egyptian cholera,” which he had previously described, and which, he averts, attacks one fourth of the population, entirely to the presence of this worm.

134. b. Symptoms.—At an early period, pallor of the face, general sense of weakness, lips and gums; palpitations of the heart, especially on any exertion, sounds heard in the jugular veins on auscultation, lassitude, debility without exhaustion, are the chief phenomena. Subsequently disordered digestion, irregularity of the bowels, and Catarrh of the intestines are complained of. These symptoms may continue an indefinite time; but if not removed by a decided treatment, the consequences are most serious and generally fatal. Emaciation often does not commence until late in the disease. (Edema of the extremities and eyelids; a pale yellowish or greenish yellow hue of the general surface; a withered, dry, flabby, and cold state of the integuments, and a profuse and copious flow of the mucous canals. Remarkable apathy, and sense of exhaustion; constant and distressing palpitations, the sounds of the heart being often heard at the distance of several feet; murmurings in all the larger arteries, and a rushing or pissing sound in the jugulars, slowly2vere. The pulse is uncommonly quick and small; the respiratory movements are weak, frequent, and short; the urine is abundant, pale, and rarely contains albumen. Giddiness and headache are commonly experienced. Constant hunger, singular appetites, and slight febrile movements, sometimes with enlargement of the spleen and atrophy of the liver, are observed. With indulgence and full diet this state may last for years; but in very many cases the progress of the malady is rapid. Even in the best circumstances the patient is pellucid and sickly, and miserable, exhibiting a high degree of anaemia and hydramia. Various acute affections often supervene and complicated disease, and a chronic diarrhoea or dysentery ultimately carries off the patient. Fatiguing labour, a lowering or apathetic treatment, and debilitating agents hasten dissolution. A restorative regimen, change of climate, and judicious treatment, often arrest the complaint. All these phenomena consequent on the presence of these parasites are characteristic of a very slow but continued loss of blood, which, if not arrested, goes on until the quantity and the quality of this fluid are no longer sufficient to sustain life; death supervening with faintness, dyspnoea, and fatal syncope.

136. c. On examination after death, the organs and structures generally are wasted, pallid and softened. The spleen is often enlarged; the liver is pale and atrophied; the veins are nearly empty; the heart and large venous trunks contain only soft, small brown capsules, with very little fibrous. In many even of the large venous trunks there is only a dark serous-looking fluid, with a few pale, large, and colourless blood-globules. The substance of the heart, especially the inner layers of muscles, are very pale and even fatty. This organ is generally large, thick, hypertrophied or dilated, particularly on the left side. The endocardium and valves are often irregular, as if thickened in parts. The brain, the lungs, the muscles, the digestive mucous surface, &c., exhibit remarkable pallor and anaemia; the cellular tissue and muscles being softened, flabby, and in parts exhibiting a watery infiltration. Griesinger imputes the "Egyptian cholera," which he had previously described, and which, he averts, attacks one fourth of the population, entirely to the presence of this worm.

137. v. The filariae.—These form the seventh genus of the first class "Nematodes," of Dujardin, and the fortieth genus of the sixth order, "Nematoides" of Grediti. From the Cordil they are distinguished by structure, mode of life, the nature of the youngest brood, and by the circumstance that they readily burst in water, like other Nematoda, which is not the case with the Gordii (Dirofilaria).

137. A. Filoria Medinensis. — Plutarch refers in the ninth question of the eighth book of his "Symposium," to the statement of Agatharchus of Cnidus, the geographer and philosopher, that "The people on the Arabian side of the Red Sea suffered many strange diseases; amongst others, worms, like little snakes (Trachyura), came out upon them, which gnawed their legs and arms, and when touched retracted themselves, coiled themselves up in the flesh, and gave rise to the most insupportable pains; but that this evil..."

* Diagnoses: "Fertiles obi, subfusi, et vulnari, corpo filiformis, clavato, cylindrico, ut plumarius aeris intus, ut epistomia radiis et cornibus dentibus suos papillis proeminentibus lateribus armata; ore terminali non labio, vel labio recto, anteriore laterali; asphypho brevi, tubuloso, sectato quam intemnibum; ore terminali aut anastomosis epigastri sina; cutis tenui at leviter oblata stromata."

** Nae: canulis pleroque obtusi, interdum membrana accessoriorum obtusa exhibebant; specios filiformes in magnis tubulosis atque lentiformibus, ut Dujardinii terrabilibus, curvulis (?). Feminae: vaginae internae proximae ad ova sita, prolongates simplex (Filariae inguinalis in filariis fere vestris, Nathouii); ovus subglobulus atque globulosus, leviusculus. Nunc ovic nunc vivipara."

† Marcus cosmetics ignitos or pustulis aliis obmorborum neglect et assuati, quin obuin marem magnam submersum efficitur et malitias et dobru et vitam omnem magnum tumorem; et nos Dujardin ita ensceu observavimus, de Calcuttana pulvere. Calcuttana pulvere."

Küchermuster.
WORMS.—_Filaria Medinensis_ described. 1403

has been found only then, and neither before nor since amongst any other people." Many authors, with much appearance of justice, believe that the fiery serpents, which Moses states to have been so destructive to the Israelites when journeying in the vicinity of the Red Sea, were _Filaria Medinensis_, and consequently that Moses is the first writer to notice this worm, and that the fiery inflammation produced by it, gave rise to the appellation bestowed upon it by the Hebrew writer.* That the _Filaria_ was considered a species of serpent by the ancients, is proved by the Greek name ἰακυτος, _draconesus_, which was given it, and by the inflammation, pain, and swelling which occurred with the breaking out of the worm. The mortality amongst the Israelites may be explained by their ignorance of the proper treatment, and of the danger consequent upon the breaking of the worm. AVENROAR states that, in his country, "Àger in continent post dolorem vehementem in parte affecta mortitur." The distemper being endemic in the place where the Israelites were sojourning (in Arabia Petra), in circumstances of great difficulty and even distress, and during the hygienic privations of encampments in a barren country, it is not surprising that it then and there assumed an epidemic and fatal character.

138. SYN. The _Filaria Medinensis_ has received a variety of names, viz. the _Dracunculus_; the _Dros., thibarum_; the _Dros., Persarum_; the _Guinac-worm_ or _O. thread-worm_; from its frequent occurrence on the coasts of Guinea; the _Guinea dragon_; the _Guinea hair-worm_; _Pharaoh's worm_; the _Skin-worm_; the _leg-worm_; the _Dracunculus_, le ver de Guinée, le ver Cutané, by the French; Guinischwer Fadenwurm; Guinischwer Drache, Pharaohswurm, by the Germans.

139. a. Our knowledge of the natural history of this worm, and of the early stages of its development, is very deficient. KUCHENMEYER states that it is of the thickness of packthread, its anterior extremity obuse, the mouth circular, without lips, but beset with four hooks, or more correctly with four styles, or acute straight spines; the vagina opens in the vicinity of the mouth, and the vagina and uterus are probably double, as in most Filaria. The length of the worm varies from several inches to three yards. Statements of greater dimensions are probably founded in error. The whole surface of the worm and its tail exhibit the well-known fine rings, placed at uniform distances.

The substance of the body is homogeneous, finely granulated, and exhibits no traces of muscular fibres. Its osseous, intestinal canal, uterus, &c., require no description.*

140. b. The worm is indigenous only in the hot zone, and, even when transported into colder climates, does not appear to propagate itself. Even in the hot zone it does not occur everywhere, but only in particular countries, like all the _Helmintha_, and is entirely in certain places in affected countries, as, for instance, in the Gambia, Angola, Canibab, &c. The places in which the _Filaria Medinensis_ more particularly occurs, are Senegal and the coast of Guinea, the East Indies, Persia, Arabia Petra, the coasts of the Red Sea, especially towards the south, the shores of the Ganges, Bombay, the Caspian Sea, Upper Egypt, Abyssinia, Nuba. It was introduced into America by Negro slaves, especially into Surinam. Throughout the countries now mentioned it attacks aborigines and foreigners without distinction. According to BRUNER the worm often becomes epidemic, in wet seasons and in marshy districts. BRUNER states that it is most frequently seen in the East Indies from November to January (the rainy season); and in Upper Egypt, according to BRUNE, shortly after the inundations of the Nile.

141. a. The mode of production of the worm is still enveloped in obscurity. English officers, who never went about with the feet and arms uncovered, remained free from this worm. BRUNER thinks that the germ of the worm is an independent marsh animal, which is converted into a Dracunculus within the human body. FÖRKS believes that he found the brood of the Dracunculus free in the red, ochrey mud of the drying marshes. However, the aborigines think that it comes from the marshy grounds into the skin. The ordinary seat of the worm is the sub-cutaneous fatty tissue, especially of the lower extremities, around the ankle. It may, however, occur under the skin and muscles in all other parts of the human body. Instances of its occurrence in other parts of the body besides the extremities are recorded by KAMPFER, BAJON, BAILLE, PÉRÉ, and have been seen by myself in Africa. M'GREGOR, in 172 cases, states that it occurred 124 times in the feet, 33 times in the lower, 11 times in the upper part of the thigh, twice in the scrotum, and twice in the hands. PÀUFER found a specimen behind the liver, between the layers of the mesentery. Sometimes the worm lies coiled up in a small space, sometimes it is extended; and in the latter case, if it lies on the surface, it feels as a Vanessa vein. PÉRÉ saw it lying in a snake-like form under the whole of the skin of the abdomen and

* Upon referring to a translation of the Bible from the Hebrew into Latin, with very copious annotations, by IMMANUEL TERRELLI and FRANCOIS JUNICE (the former a learned convert and translated into Christianity, the first and second editions of which, published in London in 1590, and 1584 in quarto, are in my library), I find that he translates the Hebrew description as follows:—"Pun immolet Jehova in populo illum serpentes pesteres, quenmodum populum: facit pharaonicum populum multas ex Israel." Here TERRELLI translates the Hebrew into venomous serpents; but in a note he states, that according to the original they were fiery serpents. To this translation of the Bible and to its copious annotations, the translators of King James's Bible, and modern authors, are more indebted than has been made to appear. Upon referring further to the very rare edition of the Vulgate, also in my possession, which was printed in 1491, and known by the term "Fonibus ex Graecis," &c., the serpents are called "serpientes.—(Miss Deus ignis serpentum)," which inflicted wounds and death on many. This edition of the Bible is in folio, of a beautiful, colored paper, the text being a bright jet-black, without the name of either printer or publisher, and without the verses being numbered, but with the initials letters illuminated and coloured. These translations vary only in the term "venomous" being used by the former for "fiery;" whilst the statement in the latter, "that the eyes slumber, and that it slays men" (in Latin), is "infecting wounds and death on many," may be considered as nearer the truth, as there was no maris medium sul folly that death was always the result. Some translations, which retain the appellation "fiery," very justly explain it by stating it to refer entirely to the inflammation and pain produced by these animals.

* BRUNER gives the following systematic description of these worms: _Longissimo et albo, Articulato, litera crassa, capite atroces, ore minus, circulari, cauda radix, puncta in margine medio; culmen, subita, indicata; femine someritae, acustulis, incurva prædica; in hominis telis cellulosis subtilissimis, presenium pestum; in regionibus tropicis causis solitis._
a part of that of the chest, and similar cases of its extension are on record. " These examples will suffice to give a clear idea of this worm, of which, moreover, as many as twenty-eight, thirty, any even fifty specimens have been observed in one man." (KÜCHLENSCHMITZ.)

142. d. Diagnosis. — If the worm is superficial, with a hard substratum, its growth is seen to take place with extraordinary rapidity, from 4th it becomes several inches long in a couple of days. It is then easily killed by poultries of boiled garlic, after which it is observed with various consequencsses. Frequently the worm occasions little or no annoyance for a long time. DAMPFER and ISERT had quitted the district of these worms for 6-8 months, and WENKOCH's patient for 4-6 months before the worm betrayed itself. According to KÄMPFER and others, this latent state may continue 12-15 months, and in rare cases, even until the third year. In other instances, emaciation, notwithstanding a good appetite and absence of fever, takes place, terminating at last in fatal exhaustion. When the worm is making its way out, a small pustule appears at the point where it will break through, sometimes goose, and sometimes worm, without preliminary annoyance, or headache, pain in the stomach, nausea, fever, &c. At the point where it breaks through, inflammation, swelling, and suppuration occurs several days previously, and continues until the worm is extracted. If it lies over or near to a joint, the use of the limb is prevented, and the symptoms are still more severe. In the case of DRAEMOND, after pain and stiffness of the leg, a reddish swelling, with a black point in the center, was formed above the inside of the ankle; and at the same time he felt a firm, round, cat-gut-like substance twisted under the integuments. About three weeks after the first sensation of stiffness, he was seized with a sudden inapparent itching over the whole body, with fever, violent colic, vomiting, and purging; after which, shiverings without perspiration followed. In the mean time the swelling had burst, and a hard white substance appeared, but so deep that it could not be laid hold of, but only having buried itself deeply amongst the muscles. The cat-gut-like twisted substance formerly felt was not now present. In the following night the ankle and vicinity were much inflamed; and three days afterwards a thread was passed round the animal, and a bloody ichorous discharge continued for six or seven weeks from the wound, which healed up gradually to a small point, when the worm again came forth, and was fastened with a thread, rolled upon a stick, and drawn out twice a day. In twenty days the extraction was completed. Two or three days after the formation of vesicles on the inflamed part these open up, or are opened by a lancet, when matter, blood, and sainies, and two or three inches of the anterior end of the worm came forth. If this end be carefully pulled several inches, more often follow. All this is called around a little roll of linen, or a small stick, and fastened over the wound with a compress and adhesive plaster.

143. vi. ASCARIDES. — These worms are arranged by DEJARDIN as the nineteenth genus of the Nematoda; and by DIESING as the twentieth genus of the sixth order of the Achetaelmintha elasticus, but the Ovarii are also introduced by him into this genus. The classification of DIESING is so involved that more confusion than elucidation is the result. Refining, hair-splitting, and drawing distinctions, which are either observed with difficulty, or not at all, are not the least faults of some modern observers. I subjoin DEJARDIN's systematic description of this genus.

The only species to be here noticed is the

144. A. ASCARIS LUMBRICOIDES. — Synon.: ASCARIS gyneascarcide, DIESING; ASCARIS lumbroides, LINNAEUS; A. gigas, GOEZE; LUMBRICUS teres, Auct.; FILOSA lumbroides, ZEGER; but the Linnaean name is very generally retained.

145. a. Description. — The head of the worm is distinctly composed of three papillae, which can undoubtedly be spread out upon the intestine, in a broad, circular, sucker-like surface, in the sucking act of the worm. BRENNER has seen the opening and closing of these papillae, and described the mechanism. At the moment of opening he saw a little tube protrude from the centre, which is the true oral orifice. WEBER thinks that this is the cleft proboscis, which is erected from the oral aperture for the reception of nourishment. The true oral aperture is, however, formed by the opened lips or papillae; the
small tubule in the centre represents the introitus faucium. Its protrusion is probably as much by its own muscular structure as by the contraction of the general muscular structure of the body. The males and females may be distinguished by their form and external appearance. The abdomen of the female is slender, and uniformly pointed at the end. The male is broad, and sometimes presents, a short distance from the tail, a pair of white, delicate, projecting hairs, which are the protruded penis. If the female be pressed, or allowed to swell in water, a prolapus of these tubes (ovaries), and a discharge of a milky substance (eggs), takes place in the anterior half of the animal from the vaginal orifice. If the male be pressed, a milky juice (seminal globules) flows out in the vicinity of the anus, without the occurrence of a prolapus. The intestinal canal is whitish and muscular at its commencement; the esophagus is composed of thick layers of longitudinal and transverse muscles, and without any marked constriction, into the intestinal canal, the parites of which are thin, internally covered with epithelium, and shines through, of a brownish colour, from the brown excrement. This intestine has a muscular coat, which is connected with the abundant longitudinal and circular muscles. The external integument consists of six layers. Under the outer layer are two layers of fibres crossing each other obliquely, and two laid at a right angle over each other, and between the former and latter two a sixth homogeneous layer, which appears to contain a peculiar odorous fluid, of an oily and reddish appearance, and exhibits refractive phenomena (Küchenmeister).

146 b. Symptoms.—Very generally the host and his guests, the Ascarides, agree very well together, until, owing to causes affecting these animals, or the digestive organs of their host, a disagreement between them takes place, and various disorders or symptoms ensue. When these worms are few in number, notwithstanding their size, they often occasion but little disorder, and live amicably with their entertainers on unaltered chyme, until their numbers, changes of diet, and other occurrences produce more or less ailment. In cases where their numbers are not great, a good, or a too good appetite, is the chief injury they do; and in this respect they are much less noxious than the much smaller Ankylostoma. Great numbers of these worms in the intestines, and a firm aggregation of them into coils and knots, sometimes with the small thread worms intervening, often occasion much disorder, according to the mechanical obstacle and the irritation they may produce. Colic, Ileus, constipation, diarrhea, flatulence, congestions of the brain, especially in children, and various reflex phenomena manifested in distant parts, the internal muscles both of the trunk and of the lower extremities, are then not unfrequent occurrences. Besides the influence of inordinate numbers—of 200—300—kotted into balls, which I have expelled from the bowels of both children and adults, the irritation and the consequent effects produced by even small or numerous worms, arising from the union of the worms to states of the digestive organs of their host, to the influence of certain kinds of food, or of change of diet upon them, or to the agitation arising in them from the influence of season, and to the periodical seeking of the females by the males, much disturbance may ensue, or the worms may travel or stray into parts of the digestive canal not usually visited by them, and thus induce very serious effects; which may even terminate in death. These effects, however, will depend much upon the irritability and other circumstances of the patient, the number of the parasites, and sometimes upon the parts which they have reached. When irritations of the intestinal canal occur, and produce watery diarrhea, cholera, &c., these worms are thereby affected; they swell up, lose their powers of adhesion, and are often carried away per annum. But one or more worms may pass unusually high in the intestines, may rise through the pylorus into the stomach, and occasion retching, vomitings, &c., irritation in the esophagus, fever, delirium, and upon the discharge of the worm all rapidly disappear. But before rising so high in the digestive canal, one or more may pass into the common duct, or passes rapidly, and without any marked constriction, into the intestinal canal, the parites of which are thin, internally covered with epithelium, and shines through, of a brownish colour, from the brown excrement. This intestine has a muscular coat, which is connected with the abundant longitudinal and circular muscles. The external integument consists of six layers. Under the outer layer are two layers of fibres crossing each other obliquely, and two laid at a right angle over each other, and between the former and latter two a sixth homogeneous layer, which appears to contain a peculiar odorous fluid, of an oily and reddish appearance, and exhibits refractive phenomena (Küchenmeister).

147 The symptoms produced by Ascarides, whilst they continue in the intestine, are mechanical, direct, and reflex. The former are the phenomena of the usual catarrhal affections of the stomach and intestines (gastro-intestinal irritations) in every grade; costiveness, torpor, colic; a sense of weight, of irritation, or of a ball, or gnawing and itching near the umbilicus; disordered, rowing, and irregular appetite, and digestion, &c. The latter are bicep, subtilus of the abdominal muscles, cramps of the lower extremities, yawning, increased secretion of saliva, snuffling or tickling of the nose, but rare of the anus, unless upon the passage of a worm.

148 The question has been often entertained as to the possibility of these worms perforating the parites of the healthy intestines, and making their way into places more or less distant from their usual residence. That these worms can never perforate the healthy intestine; the structure of its head, and its thin lips being adapted only for suction and not for boring, is the opinion of Kolffmi, Bremer, Romanovsky, Berenbrink, J. P. Frank, Küchenmeister, and myself, in opposition to that of Von Sterbold and Monier. Therefore it may be concluded that when these worms are found in situations external to the digestive canal, they have reached it by some pre-existing ulcerations, or, owing further to the influence of certain kinds of food, or of change of diet upon them, or to the agitation arising in them from the influence of season, and to the
fevers; and this opinion is not limited to the Ascariides, but is extended to the flat worms, and they have argued that the worms in these circumstances are like the rats, and have the presence of deserting a sinking ship! But as the discharge of worms from a fever-patient does not occur until after the seventh day, according to Zimmern, it is much more probable that they travel from the intestines, owing to the food obtained by them being insufficient or not suited to them, and to the secretions of the intestines being injurious to them, and in search of more abundant or more suitable aliment. The ulcerations of the intestines and the morbid matter from these ulcers in the advanced stages of continued fevers, will also tend to expel or to occasion a discharge of these worms, which, when observed, may be justly viewed, both as an indication of the existence of these lesions, and of the extreme danger of the malady.

150. VI. A General View of the Symptoms produced by Worms in the Digestive Canal.
—Most of the symptoms produced by worms may arise from other causes; but a careful recognition and observation of these symptoms, of their successions, grouping, &c., are requisite for the due regulation of the treatment, and for the ascertaining of the species of worm which is present. The symptoms produced most commonly by the individual species of worm have been noticed with reference to each; but recent writers have been more intent upon the microscopic descriptions of these parasites, and upon drawing minute distinctions, &c., than upon more useful and practical considerations connected with them. It is justly argued that the discharge of the more common species of worms infesting the intestinal canal is the true diagnosis of verminous diseases; but this discharge, even in the most serious cases, may not occur without means being used to effect it; and it is by a knowledge of these symptoms, independently of such discharge, that we are led to administer the means most likely both to establish this diagnosis and to effect a cure.

151. A. The more direct and local symptoms, or those more immediately caused by worms are——a copious and variable appetite—at one time, a craving and at another hunger, or an insatiable desire of food—at other times, nausea, or cardialgia, borborygmus, loathing, retching, or vomiting, being present; a sense of weight in the abdomen, with distension, gnawing, or erision; a feeling of cold internally, or of emptiness or inanition, often with palpitations, or hypochondria, or faintness; a dragging, twisting, or lancinating pain in the abdominal region, especially near the umbilicus, or tummy, spasms, colicky attacks, tenesmus, constipation, or irregularities of the intestinal functions; leucorrhoea, and itching; or a mucous or watery exudation from the nose, sometimes a mucous discharge, tenesmus, and bearing down pains in adult females, or derangements of the catamenia, or even abortion; and in children, more especially termins, colic, constipation, and intussusception of the bowels, with various cerebral symptoms about to be noticed. In both sexes "manustupratio" is not infrequent, even at an early age.

152. The symptoms mentioned above are chiefly by sympathy with the seat of irritation, or by direct and reflex sympathy, are chiefly frequent, dry, and tickling cough; hiccups, anxiety at the praecordia, or pængent pains passing under the false-rib and at the epigastrium; a sense of something in the oesophagus, sometimes with tickling in the pharynx; partial anaesthesia and dilatation of the skin; sneezings, itching and dryness of the nose and nostrils, sometimes epistaxis, itching of the skin, without eruption; grinding or grating of the teeth, and sudden startling when asleep; subcutaneous and spasms of the abdominal muscles; partial or general convulsive movements without complete loss of consciousness; chorea or twitchings, or irregular contractions of particular muscles, especially those of the face and lower extremities; and more or less fully developed, general, or epileptic convulsions. The urinary excretion is sometimes disordered, and dysuria or frequent micturition complained of, the urine being yellow-coloured, turbid, &c., with, or without a sediment.

153. C. A general Verminous Cachexia is not infrequently present, manifested by a pale, tinct, or livid state of the features; by a sunken appearance of the eyes and a leaden hue beneath them; a general pallor, and more or less anaemia of the surface of the body, lips, &c.; a perverted state of the sense of smell, or the entire loss of smell; a strawberry hue of the tongue, or mucous spots on the tongue and about the teeth and gums; a ridger of the teeth, and a peculiar fact of the breath, sometimes a more or less evident affection of the voice and speech; a morose, irritable state of temper, vertigo, frightful dreams, timidity, somnolency; slight or slight delirium, visus serotonius, and prostration of strength. The bilious secretion is sometimes scanty, and in some cases even jaundice is observed. The abdominal secretions are very often disordered, and the functions of excretion generally impeded. These and other effects——local and sympathetic—are manifestly produced——1st., by the irritation of the digestive mucous surface, which may, in the cases of certain worms, and in susceptible constitutions especially, go on to inflammation and its consequences; and, 2nd., by the changes these animals produce in the chyme and chyle derived from the ordinary food, and upon the secretions of the gastro-intestinal surface, and upon those of the liver and pancreas. The concomitants of these, consisting of gastro-intestinal irritation and its consequences, will also contribute to the production of the latter; but it cannot be doubted that much of the nourishment which should be taken up by the intestinal surface is intercepted by these parasites, whilst a portion of the fluids, lacteal or serous, are removed from this surface by the suction exercised by these animals.

154. All the symptoms now enumerated are not observed in the same case, but many of them either co-exist or appear in succession, and are variously grouped in different subjects, so as to render a diagnosis very difficult between this and other complaints. When the cachexia, debility, and sympathetic disturbance of the brain and its functions are considerable, more especially when the circulatory fluids are diminished in quantity from deficient aliment, or impaired in quality by imperfect assimilation and depuration, the symptoms may assume in more danger, sometimes mistaken for a form either of low fever, or of gastric fever; but more correctly recognised by some of the other writers by the term worm- or verminous fever. (See also § 73.)
WORMS. — Causes and Prevention of.

155. vii. The Causes of Worms may be inferred from what has been stated above; yet it may be of use to notice some particulars too generally overlooked by the recent writers, who have insisted upon the propagation of worms by means of ova, &c., and who may be considered as having disproved the doctrine of equivocal generation — or, in other words, the doctrine of spontaneous formation. A knowledge of the predisposing causes furnishes important indications in both the prevention and the treatment of verminous diseases; for, although the obsolete doctrine of spontaneous formation rendered this knowledge of the greatest interest, inasmuch as it was founded upon antecedent changes in the constitution, yet these changes are by no means devoid of influence in favouring the development of the ova and embryos of parasitic animals. There can be no doubt, that children of weak, aged, and vitally exhausted parents; the female sex, debilitated males; and persons of all ages, who have been insufficiently nourished; or improperly fed in early life, or of a relaxed fibre or asthenic diathesis, are much more subject to worms, than those who are otherwise circumstanced. A tender and delicate state of health in early life; the use of crude, viscous, gelenious, and vegetable food; whatever tends to lower the organic nervous force and vital resistance; a relaxed and asthenic habit of body; hereditary conformation; a residence in crowded and insufficiently drained cities and towns, and at cold and moist situations, especially in those which are abundantly covered with vegetable productions peculiar to the country, and a scanty use of such condiments, as salt and hot spices, as the climate may require, predispose to the generation of worms. In places where salt cannot be obtained in quantities requisite to the wants of the economy, as in some intertropical countries, the hot spices are used in its place by the natives. Those who contend, and, from recent researches, with manifest truth, that the presence of ova is necessary to the generation of human parasites, consider that the predisposition produced by these causes favour this generation, and that robust health and a sound constitution are subversive of their development. Those who argue for their spontaneous formation believe that these causes not merely predispose to this formation, but also directly produce it; and that, owing to a weak and imperfect chylification and assimilation, or to a metamorphosis of the secretions, a material is evolved, which, under the favourable circumstances in which it is placed, and owing to a vital emanation from the body in which it lodged, assumes an organised and separate existence. These doctrines, however opposite — the former assuming, as predisposing causes, merely what the latter contends to be direct and exciting, or efficient, causes — agree in that, which is of the greatest importance to the physician: they both point out the best indications for preventing the continued, or the future, generation of worms, where they already exist or have existed, and for guarding against their invasion in circumstances which render such invasion more or less probable.

156. IV. Treatment of Worms. — The Treatment of Worms should be referred to the following • 1st, To their prophylaxis, or prevention — 2d, To their expulsion; — and 3d, To their prevention of their recurrence.

157. i. Prophylaxis.—A. As to the first of these
WORMS.—Treatment of.

... tiresly in the delicate and debilitated as in the robust and healthy; but remain, or are retained, in the former class of subjects, and become the soil in which these animals are reared.

159. C. Persons who are, or who have been, subject to verminous diseases, ought to adopt that kind of food, and to have recourse to those medicines, which their feelings and observation indicate as being calculated to distress, injure, and ultimately to destroy or eject intestinal worms. A due attention to such means is required not only for the expulsion, but also for preventing the future generation of these parasites. Another object, and one, indeed, which is the basis of the prevention and of the treatment of worms, is to determine, in as accurate a manner as possible, from the character of the symptoms, and from the examination of the faces, the species of the animal which is to be dislodged. While, however, this diagnosis receives its due attention, care must be taken not to mistake other diseases, which possess many of the same features, for those proceeding from the presence of worms. This error is likely to occur frequently, since the one class of disorders often reciprocally bear the relation of cause and effect to each other; nor will it be attended by any serious consequences, farther than from wanting appropriate direction, the treatment must be inefficient, and redundant and superfluous. It should also be kept in recollection, that worms are more apt to be generated during fevers, and during convalescence from fevers, especially such as are epidemic, dysenteric or nervous, or are gastric or exanthematosus, than in robust health, or even in other circumstances. The generation of parasitical animals in these maladies is not confined to the surface of the intestinal canal only. It is not unusual to observe the parasites, usually produced, in favourable circumstances, on the external surface of the body, become remarkably abundant during and after these fevers, especially when the diseased secretions are allowed to accumulate from a neglect of ablutions and of frequent change of linen. The appearance of animal parasites on these occasions was explained by the supposed modification of the blood, in the way above noticed (§§ 6, et seq.); whilst it was viewed, by the believers in generation from ova, as the result of a more favourable occasion being furnished for the development of the ova during these diseases.

160. One of the earliest methods of preventing and of curing verminous diseases, resorted to by many physicians, is to remove, or attempt to remove, by purgatives or drastic means, the tenacious mucus adhering to the digestive mucous surface, and which, as they believe, forms the nidus or lodging of worms; and they believe that the quantities of mucus distended from the bowels during and for some time after the exhibition of vermifuge, and other purgatives, are proofs of the accumulation of this mucus on the intestinal surface. That this mucus or sordes may be excessive, in many cases, may be admitted; but it may also be allowed, that the greater portion of this matter is derived from the irritation of the intestinal mucous membrane, by these purgatives. This method of prevention and treatment, when moderately and appropriately prescribed, may be of service in many cases; but it should not be overlooked, that the rough operation of these medicines often leaves a debilitated state of the intestines after their operation, which disposes them to generate, and prevents them from throwing off the mucous sordes and worms which these medicines were employed to remove. They cannot, by any mechanical property, or by any chemical or other influence on the intestinal secretions and excretions, always remove them from the extended surface covered by them in the manner, or so completely as, contemplated; and even, when the proposed end is completely attained, the intestinal functions are left in a more favourable condition than before, to reproduce both mucous sordes and worms, especially if any of the ova still remain unexpelled. Therefore, instead of trusting to the medicines usually employed as anthelmintics, vermifuge purgatives, alternans, &c., our attention ought to be directed (in some cases, instead of these medicines, in others, in addition to them, and subsequently to the use of them) to the adoption of remedies which promote the organic nervous forces, and the digestive and vital energies in general, thereby increasing the healthy and vigorous discharge of the various functions, and the due evolution and evacuation of the secretions and excretions from the organism. (See also the treatment after the expulsion of worms.)

161. ii. Direct and Curative Treatment.—J. P. Frank, whose experience of the treatment of worms, when he wrote on the subject, had extended to half a century, considered that drastic purgatives and anthelmintics, at the commencement of the treatment, were seldom so serviceable, especially against taenia, as more gentle measures, which, in his opinion, should be first adopted, and be followed by more energetic remedies. But the diversity not only of these medicines, and of the combinations and methods of prescribing them, bewilders the inexperienced, until repeated opportunities of observation enable him to select those means and combinations upon which confidence can be placed. Kuchenbeiner justly remarks, that, if the multitude of remedies recommended for any disease is an evidence of their want of power against it, the therapeutics of worms are extremely defective formation, in that the treatment of these parasites leaves much to be desired as respects the efficacy of the medicines prescribed for them, the pleasantness of the most efficacious amongst them, and the disagreeable effects which often accompany and follow those most to be relied upon.

162. a. The treatment of tape-worm will firstly, and more especially, occupy attention, as it will comprise the most efficacious medicines and methods which have been employed, not only for these worms, but also for many of the others which have been noticed above; and when the treatment of these latter comes under consideration, then a brief reference to what has already been stated will be sufficient. Kuchenbeiner tested a great many of the medicines recommended against taenia, by placing live tape-worms in a mixture of the particular medicines with white of egg, and by determining the time in which they died by the assistance of the teeth, or, more properly, the irritation of the intestinal mucous membrane, by these purgatives. This method of prevention and treatment, when moderately and appropriately prescribed, may be of service in many cases; but it should not be overlooked, that the rough operation of these medicines...
oil, and in a salad made with pickled herrings, onions, garlic, &c. Tin has little or no effect, or merely the same effect as the cow-itch. Electricity has no destructive action on Tenia. "It is otherwise, however, with hounso, in the infusion of which when mixed with white of egg the mixture died within half an hour of their introduction; and with oil of turpentine, in a mixture of which with white of egg, they died in 1–1½ hour. In a decoction of Brugera (hounso) mixed with white of egg, the Tenia died in 3–3½ hours. In a decoction of rad. picndae granatum, mixed with white of egg, in 3 hours; and with the same decoction, mixed with milk, in 3–3½ hours. In a mixture of extract. flicis mariis ather, with white of egg, the Tenia died in 3–4 hours. The so-called flicine (flicia acid of Lutz), mixed with white of egg, also has an energetic action on the Tenia, which die therein in the course of a few hours, and exhibit edematous swellings in various parts. The particular methods of expulsion, arranged according to the remedies, have been enumerated by Mayer, Seeger, and Küchenmeister; but the faults which this last-named writer finds with his two predecessors, viz., the too long time the methods are followed together in a disorderly manner, may also be imputed to himself, although in a less degree.

163. a. Methods with Tin.—Frack commences the treatment with the powder of tin, or its filings, given in a simple syrup, either alone, or with sulphur, or the extractum abminhit. After having pursued this plan during three or four days, allowing only a spare diet, he prescribes, in addition to the tin, a moderate dose of japa, low diet being still observed. Dupuis prescribes, without any preliminary treatment, at six, and at half-past six, in the morning, each time a powder of Nuxia, resp. Angl. Σss., Tammies purā 5i. Gi luttii (cambogia) gr. v. Elaeocoches cujuputi, gr. ii ss.; and after each dose, the patient drinks two cups of black coffee. In two hours, the worm is expected to pass off, usually with colicky pains, on the occurrence of which strong black coffee is immediately drunk. For the occasion of this treatment, a tincture of iron is advised. Becker recommends the chemically precipitated tin. According to him, it is certain in its action, does not irritate the intestines mechanically, and is preferable in doubtful cases. It is, however, difficult to be obtained. Küchenmeister protests against the administration of tin-filings, as being, in his opinion, a much too irritating medicine. But he has twice prescribed tin, precipitated from chloride of tin, in an extremely fine powder, making it into an electuary, with honey, a little extr. panic. granat., extract. flicis mariis ather., and cajoba or japa. Even young and weakly children support this remedy very well. On one occasion, the entire worm passed, dead, on the second day. In the other case, an adult, several yards passed after this medicine, but the remainder of the worm was expelled by his ordinary mixture (§ 161). He considers the medicine to be uncertain, but suitable to children of both sexes and persons who are much reduced. Tin, in various combinations, has been prescribed, also, by Alston, Mayer, Mathieu, Hautfianes, and Adestrius; but its operation, as they have prescribed it, is often either ineffective, or too irritating to the digestive mucous surface.

164. b. Methods with the Male Fern.—
WORMS — TREATMENT OF TAPE-WORMS.

three drachms of finely powdered fern-root. This is taken in the morning fasting, either at once, or in three portions at intervals of an hour. In three or four hours, sickness and disorder of the stomach ensue; and then, calomel, freshly prepared sulphate of iron, aq. gr. x.—3j., according to age, are administered, and repeated if vomiting occurs. The worm is said to be generally expelled in the evening; when this is not the case, a rich gruel is given on the same evening; and on the following morning fasting, rhubarb and jalap, aq. gr. x.—3j., is repeated.

167. (d.) Albright’s and Dubois’ methods are nearly the same, and as follows: — After a preliminary treatment for eight days, to which garlic, roasted under the ashes, is added, the abdomen is rubbed with several days a day with a liniment of camphor, with balsams and nut oil, and with crushed bulbs of garlic, also a pisanes of helminthocoront and filis mus, and a nightly enema of marsh-mallow water are without this preparation, Albright prescribes —

This is to be drunk in cupfuls during the day. After three hours of repose, calomel and corn. corv. unti., of each gr. ij., made into a bolus with conserv. rose q. s., are given. In the evening, 3j. of oil of sweet almonds; and on the second day, the following purgative:

No. 281. R. Scammonit, gr. xviiij. — Rad. Filipic Maria, 3j. i. — Camboget, Calomet. 2a. gr. xiiij. M.

To be taken in three portions in sugar and water. Denous, after the preliminary treatment just noticed, prescribes, early in the morning, 3ss. of filis mus in broth; and every half-hour of the following:

168. (a.) Biching’s and Singer’s methods. The former commences with draughts and clysters of cold water, and with full diet and cold baths. With this diet, diet, but without the cold water, according to Sekren, a saturated decoction of 5ss. of fern-root is drunk cold after each meal, when the worm will be expelled in from three to fourteen days. Sekren’s plan, according to Küchenmeister, is suited to irritable and weak persons.

169. (f.) Nuffer’s and Osier’s method. The evening before the treatment, the patient takes a thin gruel with two ounces of butter; a quarter of an hour afterwards, a glass of wine, and, if necessary, a clyster. The next morning fasting, 3ij. pulv. fil. maris in 3iv. —2vj. aq. lfbas. If vomiting occurs, this is to be repeated; and if sickness be left, black coffee is taken. Two hours after this, the following bolus is given:

For weak patients and children, in two doses. If the bolus be thrown up, or not have operated in case; and then calomel, freshly prepared sulphate of iron, aq. gr. x.—3j., of Epsom salts, dissolved in warm water, are given. If the worm be not expelled by this, the gruel and powder are to be repeated, but the Epsom salts are to be given instead of the bolus. Other directs a table-spoonful of castor oil in meat broth every half-hour instead of the bolus. This treatment is said to be certain against Bothrioccephali.

170. (g.) Blagrove’s and Rapp’s method is much praised. The previous evening, a thick mixture of bread and milk in the following morning 3j. pulv. rhab. fil. maris is given every hour, in an ounce and a half of nutmeg tea. After six or eight doses, the worm is expelled. Rapp directs the root to be fresh, and administers 3vij.—2j. of it one dose.

171. (h.) Mayor’s method. Mayor, of Geneva, regards the root of filis maris as specific against Bothrioccephalus, and tin and powdrous root against Tenia solium, and states that the powder of the fern-root should appear quite green, as it is otherwise inoffensive. He gives 3ij.—3 iv. in a mixture of balm tea and 3j. of gum syrup. This draught is to be taken at night, and 3 jas. of castor oil the next morning. Mayor, in some cases, instead of the powder, prescribes the oleum filicis maris in the form of pills, —thirty to fifty drops in twenty-four pills, of which twelve are taken at night, and twelve in the morning, and an hour afterwards 2jas. of castor oil. In other cases, he gives the fern-oil either pure, or mixed with castor oil, in doses of 3ss.—3j.; but usually the castor oil afterwards.

172. (h.) O. Bang’s method. For three days, the patient takes only one basin of meat broth, with white bread. At night, he has a claster of warm milk. On the fourth day, he takes the eight cups of black coffee with plenty of sugar, and two to three large pickled herrings in the form of salad, with plenty of vinegar, pepper, oil, and onions. On the fifth day, he takes alternately, every two hours, one third of a claster, and a heaped teaspoonful of pulv. rad. filicis maris, and with this two to three cups of coffee. At night, a milk claster and a dessert-spoonful of castor oil. On the sixth morning, fasting, two teaspoonfuls of flour-powder; an hour afterwards, two table-spoonfuls of castor oil, and the same quantity every two hours until the worm is expelled. During this he drinks tea; and, luckily for the subsequent treatment, iron is more harmless.

173. (h.) Ullersperger’s method. Without any previous treatment, he gives 3ij. —3 iv. of the bark of the roots freshly peeled, treated with alcohol the day before, and left the patient lie in bed. When no vomiting takes place within two hours, an anoint of 6gr. calomel and 3j. of capo jalap, in pills is given. This method is said to be rapid and efficacious.

174. (h.) J. P. Frank’s method is to commence either with the exhibition of tin, as above, and to follow with the male fern, or to begin at once with this latter, giving about three draughts is a draught of cold water, and to give frequently cold diluents, allowing the most rigorous abstinence. A dose of castor oil may be taken the following day, and repeated every two hours until copious evacuations are procured.

175. (m.) Mager’s and Karsten’s methods. On the day when fragments pass off spontaneously, the patient takes a herring salad at night. At six o’clock next morning, 3ij. of flour-powder in 3vj. of ap. flor. tilse is taken in ten spoonfuls without stopping, and immediately after this a table-spoonful of castor oil, and then a cup of thin broth. The oil is then continued every half-hour until 3ij. are taken. For any sensation of fullness and nausea,
WORMS — TREATMENT OF TAPE-WORMS.

be taken at bed-time, containing three grains of calomel, and eight of compound colocynth pill; the following morning, a dose of castor oil. A little broth only should be given till the bowels have been thoroughly cleared out. As soon as that object is effected, one dram and a half of oil of male fern is added, but in Swan's contained as much aromatic water; and the dose of oil of male fern is to be repeated in six hours, if the first dose has not proved efectual before the expiration of that time. For a child, calomel and jalap may be substituted for the colocynth and calomel. The dose of the oil of male fern must be as large for the child as for the adult; seeing that its action is on the parastis, and not on the patient, I have never seen any unpleasant results follow its employment in the child. I have, in several cases, given the male fern successfully, when connected, many years ago, with public medical institutions; and since the publication of Dr. Jenkyn's interesting paper on the use of the atheral oil of male fern, I have prescribed it in two cases — in one with complete success, but in the other it failed. In this latter, the oil of turpentine and the kouso had been prescribed separately and after considerable intervals, and both had failed, portions of the worm only having come away. An opportunity, however, was not afforded me of persevering in the treatment beyond the exhibition of two doses of two drachms each. The oil was procured from an undoubted quarter. I give, in the subjoined note, Dr. Jenkyn's account of his experience with this oil. In a case, recorded in

hot black coffee is given. About twelve o'clock, the greater part of the worm is expelled, and the head passes at one or two o'clock. Bitters are prescribed subsequently. — KASTEN'S method consists of a mild aperient and scanty diet the day before; and early in the morning, 3 iij. of fern-root in teaspoonfuls. If the worm is not seen on the following day, a second dose is given. Between eleven and one o'clock, the worm is expelled without any further treatment. Several other methods of employing the male-fern root have been enumerated by KÜCHNENSTEIN, generally premising various means, the modus operandi and utility of which, are not very apparent. I shall next notice two other preparations of this root — the extract and the atheral oil, which have been used with great benefit. The compound decoction of male fern, for which I have given a formula in the Appendix, will be found one of the most efficacious modes of prescribing this remedy. (See Form. 62.)

176. (n) The extractum filicis maris has been prescribed by several physicians. PESCHER administers it as follows: —

To be taken in two portions half an hour before bed-time, after fasting from five o'clock in the evening; next morning an aperient. Several physicians have adopted this preparation and its mode of exhibition with success. KIRNER and HELLER gave the extract, for several days together, to the total amount of 5 jiss. with good results. After several days of spare diet, MÖHNE gave fifteen of PASCHE's pills to the fasting patient without mixture, and made it into pills at half-past nine. His prescription is as follows: —

After the last dose, he gave 3 jiss. infus sativus compus, at once. FERG administered the extract night and morning with syrup and gum, and afterwards gave castor oil every hour until it operated freely. NOSS prescribed an aperient on the preceding day, and the extract to the fasting patient with syrup; he gave the extract twice with an interval of an hour; then castor oil of purest distillation. ALBEE, after a restricted diet for one to three days, and on the day before the exhibition of the extract, prescribed a purgative of Glauber's salts; and on the following morning, 56. of extract of male fern whilst fasting, and the same quantity an hour afterwards — one to two hours afterwards, castor oil. RAYNER gave seventy-two drops of PASCHE's thin extract of fern made into pills with the powder of the root, of which eight are to be taken at night, and eight in the morning; two hours afterwards, castor oil. MALENIE prepared a tincture from the buds of the fern, and made it into pills with the powder of the bark of the root, each containing a drop of the tincture. From eight to twenty were said to be sufficient for expulsion of the worm. The circumstance of no further accounts of the employment of this tincture having appeared, seems not in favour of its efficacy.

177. (n) The atheral oil of male fern has been much employed and praised by Dr. JENKYN. He caused the patient to be kept without food for sixteen or eighteen hours, before he gave the oil; and he further recommends the following mode of administering it: — "For an adult, two pills may
most generally used, but I prefer the extract. The best method of preparing this is as follows: —

No. 367. B. C. Cortis leviter contulit Rad. Punicis
Granati, §i vi; maceratam per horas xxiv. cum aqua destill.
8. j. j.; postea coque in lenti calore per horas vii,
ad remanentiam 3 j. et coele.

To be taken in three to four doses at intervals of from half an hour to an hour. — 7th. According to German physicians, the fresh bark, or the extract prepared in the East Indies from the fresh bark, is to be preferred. Even the fresh bark, cultivated in Germany and in green-houses, is more efficacious than the dried bark. Waine’s extract, prepared from the fresh bark in the East Indies, is very active; the dose of it being 3 j. — 8th. The ‘most efficacious form, under all circumstances, is the solution of the extract in a certain quantity of water. The extract itself, made into an electuary with honey, or administrated in pills, is to be recommended where there is great tendency to vomiting; but on the whole, in aqueous solution is the best. — 9th. An alcoholic extract is also recommended by Dippleus, and recently by Martens; and an alcoholic extract has been prepared by Waite in Java. Of the latter, 3 j. — 3 j. are administered in 3 j. of fennel water with syrup corisici aurantium. 3 j. in three doses, at intervals of half an hour. — 10th. Although boiling water is, to a certain extent, sufficient for the preparation of the active substance of the bark, yet the addition of caustic potash or soda, or of a little white wine to the water employed in the maceration, and afterwards in the decoction, of the bark, greatly increases the efficacy of the extract. — 11th. Bark which has been long kept is to be rejected as infeecit. — 12th. Kchenmeister has recourse to another method of preparing the decoction and extract besides that advised above (6th). It is as follows: —

No. 387. B. Cortis leviter contulit Rad. Punicis
Granati, 3 j.; Pulv. Rhamni Cathart. 2 j.; Aquae Destill.
12 j. 14 j.; coque lenti calor in balneo vapor, per hora 3 j.
ad remanentiam extracti.

The woody parts are to be removed by washing and pressing some time before the conclusion of the evaporation; the washing water is to be separated with the rest. A quantity of this extract, corresponding with the dose of the pomegranate bark prescribed, is to be dissolved in 3 j. — 3 j. of hot water; and, before administration, 3 j. — 3 j. of extracts siciliae marii aether, may be added, when it is desired to combine the two extracts. (See § 176.)

179. d. Methods of Preserving Pomegranate Bark. (a.) Recent bark. — Buchanan prescribes 3 j. of fresh bark of the root to be boiled with three pints of water until two pints remain, and drunk in cupsfuls, at short intervals, until the wound is expelled. Kchenmeister says that, by this violent vomiting, colic and purges are produced. Breton recommends 3 j. of the fresh bark to be boiled down from 3 j. to 3 j., or, according to Gomez, from 2 j. of water to 2 j., and this decoction to be taken by mouth. Moly adv. 3 j. of fresh bark to be infused night in 2 j. of water, and left to macerate through the night, and to be boiled down to 2 j. in the morning. After being filtered and well pressed, this decoction is to be taken in three equal parts within two hours. If vomiting occur after the first dose, this should not prevent its
following doses from being given; but if the patient vomits these, the treatment must be desisted from. According to SCHMIDTMULLER, after one day’s fasting, and the administration at night of 1/4 of castor oil, 1/8 of fresh bark are macedrated for twelve hours in 2/3 of water, and concentrated to 5/6; this is taken in three doses within an hour. KUCHENMEISTER remarks that in all these methods, evacuations take place without purgatives, as the fresh bark usually acts as an aperient itself; and in this lies the great advantage of the fresh bark, and a principal cause of the great uncertainty of most of the previous methods, in which the dried bark was employed. To produce the aperient action with certainty, the dried bark needs the addition of purgatives. According to my experience, the neutral salts and the true drastics, such as jalap, are greatly to be preferred to the oils. The decoction of fresh pomegranate bark may also be prescribed as stated in the Appendix. (See Form. 69.)

180. This writer prefers the extract. radicis punice granatii, prepared according to the prescription given above (§ 178. No. 387.), to all other remedies for tape-worm with which he is acquainted; for, in almost every case of expulsion by this medicine, the worm was passed in one piece with the head, or unbroken and in a single coil sufficient reason, in his opinion, for endeavouring to make the administration of this remedy more agreeable, and its results still more certain.

181. (b.) Combinations of pomegranate bark and male fern.—This was attempted by VON KLEIN, and afterwards by KUCHENMEISTER, the latter prescribing it as follows:

A cupful to be taken in the morning fasting; a similar dose in three quarters of an hour. The third is kept in reserve. If the worm be not expelled in an hour and a half after the second dose, the last portion is also to be taken. If vomiting occurs, a tablespoonful of the medicine is given every ten minutes; and, to alleviate the tendency to vomit, the patient is recommended to gargle, after every dose, with fresh milk, without swallowing any of it. Small pieces of candied citron or lemon-peel are allowed between the doses. If no evacuation has occurred three hours after the first dose, and the worm have not been expelled, an aperient is administered. "With nemis solutum, castor oil is usually sufficient; one to two tablespoonfuls every half-hour or hour; or:

To be repeated in two hours, if required." With T. medicoacellata, this writer has found the best results with the following aperient:

To be taken at once. After the expulsion of the worm, he advises no treatment, except tonics in cases of great weakness.

182. (c.) The preliminary treatment, advised by KUCHENMEISTER, is as follows:—At the seasons of fresh strawberries and grapes, he gives half a pint of these fruits every morning, fasting, for six to eight days; and on the evening before the expulsion, a herring salad with plenty of vinegar, onions, raw and boiled ham, and plenty of oil; and to very costive persons, 1/5 of castor oil; after which the patient may drink a large glass of light Rhenish wine, of a glass of bitter beer. If the fresh fruits are not to be had, the salad alone will suffice. In this case, the medicacoacellata, he allows the patient to take as much confection of senna with tansy-cul vulgaris, (3 iv. to the ounce of the confection) as will produce two soft motions daily; then he takes the mixture, and not before. Fasting the night before is not advised, as the medicine does not agree well with an empty stomach.

183. (e.) Methods with Oil of Turpentine.—I have prescribed this medicine both as a preliminary means variously combined, and as a direct remedy, or after little or no previous treatment. As a preliminary medicine, I have most frequently used the following form:

Cold water, or linseed tea, barley water, &c., may be taken frequently during the continuance of this medicine; and in some cases, as soon as any indication of disorder of the urinary functions occurs, a full dose of either castor oil, or of calomel with camphor or jalap, so as to freely evacuate the bowels, should be given. Frequently a considerable portion of the worm is expelled by these means; but, nevertheless, the male fern, or its oiletheral oil, or the pomegranate bark, should be taken, as prescribed above (§§ 164 - 181.), a few hours after the exhibition of the purgative; or, in other cases, a few hours before, especially if the bowels have not been long conformed.

184. KUCHENMEISTER states that "the dose of this remedy is 3 j., at once, in the morning, fasting; and, if no stools result, another 1/5, afterwards (FENWICK and COPLAND); or 3 j., olei terenthini, made into an electuary with honey, &c., in two doses at night before going to bed (THOMSON); or 3 j. - jias. (SCHMIDTMANN); or with the olei filicis maris (MAVOR). Or the patient, for three days, is allowed to eat only water-gruel with small portions of white bread, three times a day; and on the next day, when fasting, to take the following:

- No. 392. B. Olei Terenthini, 3 j. - sum Vit. Ovirum, 1. - 1. Soc. Albi, 3 ss. M. and if the worm is not expelled on this day, the dose is repeated on the following day (MAVOR). Some also give 3 j. - jias., one half in the morning, and the other at night." This is one of the most effective agents against tape-worms, as LANG, KUCHENMEISTER, and others admit. The latter of these writers states that tape-worms had in turpentine mixed with white of egg, died within one hour and three quarters; and that the touchstone of a remedy for tape-worms is not whether it expels Bathrocephalus laurus or Nemis solutum, but whether it is also capable of expelling the T. medicoacellata. That the oil of turpentine is efficacious in the latter case, he can prove; for the finest specimen of this last-named worm was ex-
WORMS—TREATMENT OF TAP-WORMS.

... propelled by it. In general, it acts with tolerable rapidity, and entirely. This latter circumstance he regards as a requisite of a good vermicide in cases of tape-worm, especially as the doctor and the patient are anxious to ascertain the expulsion of the head of the parasite.

In this condition, objections to this substance are its nauseous taste, the inclinations to vomit, the unpleasant eructations, griping pains, and disorders of the urinary excretion, it often occasions. It more frequently produces these unpleasant effects when taken in the form of an electuary. When prescribed in the form of mixture, as above (§ 183.), or suspended by white of egg, or taken either pure in a full dose (§ 5 j. — 7 j.), or with the addition of castor oil, on the surface of coffee, or milk, or on any aromatic water, at bed-time, or early in the morning, it is generally the most efficacious, and least likely to produce any of the above unpleasant symptoms. It is often taken, with less discomfort, on the surface of Hollands or common unseasoned gin. When castor oil is not given with it, and it does not act on the bowels in a few hours, either a full dose of castor oil, or of some one of the purgatives already mentioned, should be taken with facility and Majesty.

186. §. METHODS WITH KOUSSO.—Kousso — flores kousso — the dried and powdered flowers of the Brugerea anthelmintica, has lately been much in vogue against tape-worm. It has been supposed, by several physicians, to have been adulterated. Kichenmeister supposes that it is not so much adulterated as mixed with other Abyssinian medicines against tenia, as with the powder of the root of Verbascum ternaca, and with the powdered leaves of Jasminum floribundum. The dose of the powder of kousso is 3 vj. to 5 j. I have prescribed this remedy in four cases. In the first, successfully in the case of a medical man in Hertfordshire; the entire worm with the head having been brought away, after turpentine and some other anthelmintics were said to have failed; but in two cases, with only a partial benefit; and in one case, without any effect. The writer just mentioned was not, or could not, or was less unlucky with this remedy, which, in the ordinary mode of administration, shares all the defects of the other remedies for tape-worms, and easily produces sickness and violent pains in the intestines; and that the worm has generally been expelled by it in numerous fragments, and at most the worm up to the neck; but that he never found the head, excepting once, after a second dose of the kousso, which caused violent pain in the abdomen. Several attempts have been made in Germany to isolate the active constituents of this substance, and to prepare infusions, decoctions, and infusion-decoctions of it, with and without the flowers being retained in them; but, although the effect appeared to equal or to approach that of the powder of kousso itself, yet little was gained, excepting when the quantity (5 vj. — 7 j.) of kousso usually employed was macerated in cold water for twenty-four hours, and then boiled for half an hour, and the whole taken — without straining — with the flowers in it, in two portions; 3 j. to 5 j. of castor oil having been given two hours after the second portion. This infusion-decoction was said to have been well borne, and to have acted with certainty.

187. §. NOTICES OF SEVERAL OTHER MEDICINES AND METHODS AGAINST TAP-WORMS. — (a.) The Spigelia anthelmintica has been employed, according to Novis, in the West Indies; but its effects are unpleasant, and it not easily admits of use in Europe. — (b.) Sabadda has been given in a dose of half a dram of the powder in the morning, the patient having been purged on the previous day with rhubarb and Glauber's salts. The sabadda powder is given with the same quantity of fennel sugar, and the patient afterwards drinks one to two cups of chamomile or elder-flower tea. If vomiting be produced, worms in the stomach are thrown up. On the second day, the same dose of sabadda is taken; and if no more of the worm appears, half the quantity of this medicine is taken morning and evening of the third and fourth days. On the fifth morning, whilst fasting, a purgative is administered, and the living or dead worm is brought away. For children from two to four years, two grains of sabadda powder is a sufficient dose. This medicine is of service against ascarides. — (c.) The schedel — the Phytolacca dodecandra or Abyssinia. The fruit of this plant has been tried in Europe, and fragments of the worm have been brought away; but sufficient trials have not been made of its efficacy. — (d.) The fructus sauvie, the fruit of Massa pieta, Hoehstetter, has been given in doses of 5 j. — 7 j. with uncertain results. This remedy is easily taken. Its taste is less repulsive than that of other remedies. Nausea, vomiting, and slight pain in the abdomen are often experienced from it. In two cases, the worm were expelled by it up to the head, but always in fragments. This remedy appears to be deserving recommendation for ascarides and oediquades. — (e.) The Municha — cortex muncis — from Municha anthelmintica. The dose of the powder is 5 j., and is usually, in the East, given with honey in a soft paste. Single fragments of the worm were brought away by it, but the medicine was probably injurious by keeping.

188. §. DRASTIC PURGATIVES WITH AND WITHOUT CALOMEL. — Bremer's and Schmidt's methods of employing these medicines are too severe, and are often made more so by the digestive mucous surface, which may not be allevied for some weeks. I will not, therefore, mention them. According to Etzmüller's plan, the patient takes, at seven o'clock in the evening, calomel. gr. xij., lapid. cancror. 3 j., and about nine o'clock, olej. amygdal. dalc. j. juss.; which usually operate twice the night. At seven and nine o'clock next morning, he takes camboget. gr. xij., rad. valeriane, and sem. cinam. 3 j., gr. iv., when the worm is afterwards expelled. I much doubt this result. It is quite unnecessary to state the various modes in which the changes are made upon the purgatives believed to be most appropriate in cases of tape-worm, by writers of no mean reputation, and the several ways these medicines may be combined, and successively administered. Calomel, cambrage, jalap, castor oil, the sulphates of potash, soda, magnesia, &c., variously concocted or administered in combinations with or without valerian, oleum tannic, &c., are the chief medicines advised. But, in order to be efficient, their doses, and the repetitions of them, are such as to risk the supervision of inflammation; and in a large proportion of cases they fail altogether.
189. ii. Inferences. — (a.) Simple methods of treatment with the *filis mus* and its *etheroil* oil and extract (§§ 176, 177.), are sufficient to remove the *Botthioecephali.* — (b.) For the expulsion of *Tenia solium,* the combination of the aqueous extract of the bark of the pomegranate root, with the addition of the extract of mealworm, is considered by *Küchenmeister to be the most efficacious, camboge, gr. iv.,—vii., being preferable to the saline addition mentioned above. — (c.) The *Tenia meleagrellae* is generally expelled by the same combination, especially when a powder with coloconel and jalap, or camboge, is given afterwards. — (d.) In very obstinate cases, the methods with tin, or those with turpentine, or with these latter following the former, may be employed with care and circumspection. — (e.) The kousso does not promise any advantage over the above remedies, if, indeed, it be equal to any of them. — (f.) When the worms depend from the mus, the German physicians adhere to a cup of strong black coffee with plenty of sugar to be given immediately. A dose of coloconel and jalap, or this followed by castor oil, appears to be more efficient.

190. k. Treatment with Kamala (the red powder obtained from the copules of Rottleria tinctoria, Roxburgh). — This substance, long known in India as a valuable dye for silk, has been much employed against tape-worm, which is very prevalent in the Punjab and North-western Provinces of India, and has recently been prescribed with success in this country by Dr. Leard and others. This peculiar red powder may be prescribed in doses of half a draught to three draughts suspended in water. “A single dose is often found sufficient, and in general it is not necessary to give any other medicine before or after. In some cases, however, where a small dose of kamala has been administered, castor oil has been afterwards given with good effect.” Dr. Gordon has prescribed kamala in the dose of one draught, repeated at intervals of three hours. Kamala may be given also in the form of tincture, the formula for which, recommended by Dr. Anderson, is as follows:—

No. 209. B Kamala, 3vj; — Spiritus rectificatus, 3avj. Macera pro boloam et cola.

An atherial tincture may be prepared of the same strength; but it is said to offer no particular advantage over the alcoholic. The dose of *tinctura kamala* is from 3j, to 3iv., diluted with some aromatic water.” (Dr. Hamlyn, in *Pharmaceutical Journal,* Feb. 1859, p. 405.)

191. Drs. C. MACKINNON, Anderson, Corby, and Gordon have praised the anthelmintic powers of this medicine. Dr. Mackinon states, that the results have been so satisfactory, that he has had occasion to employ this with even success in cases of tania presented itself, and that he has given it in sixteen cases without a single failure. In none of his cases, excepting one, did he ever exceed, for a single dose, three draughts. This dose usually purges from five to seven times; and the worm is usually expelled dead in the fourth or fifth stool. In less than half the cases, some degree of nausea and slight griping were experienced; in the remaining half, no inconvenience whatever was felt. Dr. Mackinon states the following as the results of his experience of this medicine:—“1st. That kamala is a safe and effective remedy for tape-worm, and more certain than either turpentine or kousso; — 2d. That, to a strong European, three draughts may be safely given as a dose; — 3d. That, to a person of feeble habit, or to a female, one draught and a half, followed, if necessary, by half an ounce of castor oil, is a sufficient dose.”

Since the above was published, Dr. Mackinon has administered this medicine to nearly fifty patients, and in two instances only was no worm expelled. (Medical Times and Gazette, Dec. 19, 1857, p. 628; and *Indian Annals of Med. Science,* vol. iii. p. 86.)

192. Dr. Anderson states, that “after three draughts of the powder (of kamala) have been administered, the worm is usually expelled in the third or fourth stool. It is generally passed entire, and almost always dead; and in all the cases I have examined (about fifteen), I was able to detect the head. In only two cases do I know of the worm being passed alive. The advantage of the tincture over the powder consists in its action being more certain and milder, and in its being rarely accompanied by nausea and griping. In two or three cases, only two or three stools followed the dose usually given, and the worm was expelled in the second stool; in one patient, only one stool was caused by the medicine, and in it the worm came away dead.” (Ind. Ann. of Med. Sci. vol. iii. p. 82.) Dr. Anderson alludes to ninety-five cases of tape-worm, in which kamala was prescribed, and of this number (eighty-six were European soldiers) he was aware of only two in which no worm was expelled. Dr. C. A. Gordon remarks, that “with this medicine there is no unpleasant effect. It is not even necessary to take a dose of purging medicine as a preparative; and, beyond a trifling amount of nausea and griping in some instances, no unpleasant effects are experienced; while by far the greater number of persons to whom it is administered suffer no inconvenience whatever beyond what they would from a dose of ordinary purging medicine.” (Med. Times and Gaz. May, 1857, p. 429.)

193. Dr. Anderson and Dr. Gordon agree in stating that the frequency of tania in the North-west and Upper Provinces of India arises from the free use of animal food of a very unwholesome character by the European soldiers; whilst among the Hindu natives, whose food is entirely vegetable, this parasite is unknown. Foul-feeding and half-starved pigs, cattle and sheep, as well as ducks, turkeys, fowls, pigeons, equally foul-fed and diseased, are often made articles of diet by the European soldiers, and are justly viewed by the physicians mentioned above, as the causes of the prevalence of tape-worm in this class.

194. iii. Treatment of the Other Worms.

— A. *Echinococcus, cysticeri,* and *ascophalax,* rarely admit of treatment, and only of surgical treatment. This subject is sufficiently noticed in the article HYDATID.

195. B. The comparative rarity of the *Distoma hepaticum* (§§ 96—100.), and the difficulty of its diagnosis, render the prophylaxis and treatment of this worm matters of subordinate importance. The prevention is either difficult, or impossible, owing chiefly to our imperfect knowledge of its developmental history. As far as this history may be inferred from the subjoined remarks of *Küchenmeister,* the prophylaxis must be founded on it, and be
WORMS — TREATMENT OF DISTOMA, OXYURIS VERMICULARIS, ETC.

viewed as conformable with what has been stated above* (§§ 157—160.). The direct treatment of Distoma hepaticum can rarely be ventured upon with success, owing, first, to the almost impossibility of its diagnosis, unless its presence be inferred from the passage upwards or downwards of some individuals of this species; and next, from the serious nature of the lesions produced by it. Even granting, then, the detection of the malady, medicines can be exhibited only with great uncertainty as to their beneficial effects. As, in many of these cases, the biliary functions are more or less interrupted, and organic vital force impaired, it becomes necessary to attempt the restoration of the former, and the development of the latter, by suitable means. To remove biliary obstruction, calomel and other mercurial preparations combined according to the peculiarities of the case; the nitro-muriatic acids internally and externally; the preparations of taraxacum, and the mineral waters of Carlsbad, Marienbad, Kissingen, and similar springs. Durand's medicine against gallstones and obstruction of the gall-ducks has also been recommended. This medicine consists of equal quantities of oil of turpentine and sulphuric ether. It may be given in moderate and frequent doses; or the oil may be conjoined with alcohol, or with nitric ether, or with the sweet spirits of nitre. These appear to be appropriate for this parasite, as the efficacy of the turpentine against other forms of the rapidity of the absorption of it into the circulation, are indications in favour of the use of it, in cases where the existence of this animal is inferred. Kuchenmeister states that the principal ingredient of the remedy of Durand has been successfully administered for distoma of some of the lower animals; and that, upon his recommendation, turpentine was administered to several sheep, and followed by a purgeative; but the results were not fully ascertained when he wrote. The propriety of enabling the constitution to throw off the parasitic animal by the exhibition of tonics conjoined with alternatives and debriestants, and such as the bi-chloride of mercuric, with preparations of cinchona; the extract of taraxacum with the solution of potash, and with tonic and bitter infusions or decoctions; and the nitro-muriatic acids with these latter and with taraxacum, cannot be reasonably doubted.

196. C. The Distoma hepaticum, so remarkable

"Although it is still unknown to us how the embryo becomes metamorphosed, and into what cercariae-race or rozkis it is converted, and where these cercariae-races or rozkis live; although we do not know whether the brood of D. hepaticum is called or not, and where it encysts itself, whether free in the water in the manner of Monostoma, in aquatic mollusca or insects, or in higher animals which occasionally visit stagnant waters—yet there is much probability that the herbivorous or omnivorous domestic mammals infect themselves with free encysted young Distomas, either by devouring snails which adhere to the grass of the meadows, especially in moist pastures, or by drinking from impure, stagnant waters (marsh or pond water). Exactly the same thing would then take place in man, by means of snails adhering to shells, in turnips, radishes, turnips, and other roots. Nay, such small snails might even be introduced with dry fodder into the stomachs of our domestic animals during the winter, by their eating the small species, passing their winter sleep in their closed shells, or the shells of the snails. And so, intermitting to roots protected from flood in warm cavities or cellars. Whether the production of D. hepaticum, or the mode in which it takes place by drinking impure water, must remain quite undecided. The finding of young Distomas, in the sole of a woman's foot, appears to be in favour of an immigration, and a mode of existence similar to the Cercariae."—(Op. cit. p. 270, l.)
WORMS — TREATMENT OF STRONGYLUS, ANCYlostomum, ETC.

The aloea, in combination with sulphate of quinine, acts energetically on the bowels; therefore the enemata are regulated according to their operation; a larger dose being given for the expulsion of the different species of ascariides; and the smaller doses for the prevention of their regeneration. The enemata already recommended should also be administered after the pills have been taken during two, three, or five days, the repeated exhibition of these latter rendering the former more efficient and generally successful.

189. *The Strongylus gigas* (§§ 128—130.).

This worm, which is found chiefly in the kidneys and urinary bladder, can hardly be inferred to exist during life, unless its discharge takes place, which very rarely occurs. Küchenmeister remarks that, if several worms, or one large female, be present, the urine is turbid, the bladder enlarged, so that the enlargement may be detected by palpation, percussion, and perhaps by inspection; but the cause of this swelling, or any flow of blood from the urinary passages, or of any existing retention of urine, could be referred to the presence of these worms only when any of them are passed from the bladder; and in this case, the treatment would be chiefly to alleviate irritation by mucilaginous and oily medicines, and emollients, demulcents, &c.

The oil of turpentine, internally and externally, may probably be of use in some instances.

200. F. The *Ancylostomum duodenale* (§§ 132—135.) is one of the infestations on Egypt and some other tropical countries, and to BRENNER we are indebted for all we now possess respecting it. Unacquainted at first with the real cause of the disease which it occasions — with the prevalent anaemia, chlorosis, &c., produced by it — he had prescribed for it black pepper, cinchona, quinine, calomel, nitre, cloves, stramonium, calamus, camphor, salt, &c., in gruel, according to the peculiarities of the case. The mist: ferri may thus be conjoined with the decoctum aloes com- pos. or with the tinct. aloes; or the pilula ferri comp., or sulph. ferri, may be given with the pilulae aloes cum myrrha, the pilulae gallbani com- pand camphor. Electuaries may also be prescribed in other cases, with the carbonates or oxides of iron, the antimonial, and concoction of senna, with a small proportion of the concoction of black pepper; and, if these do not completely remove the annoyance, the use of the enemata already recommended should be adopted (see Form. 71, 80, 105, 106, 149, 151, and 153). In some cases where these are required, the long flexible tube should be introduced above the sigmoid flexure of the colon, so that the remedies may reach above this part of the bowel. Having removed the worms, it will be well to prevent their regeneration, to continue the use of the preparations of iron in conjunction with aperients and the other medicines which the circumstances of the case will suggest. The following pills have been found by me, for many years, to be most successful in removing and in preventing the re- generation of the *oxyuris vermicularis* and the *ascariides lumbricoides*, both of which are parasites are often present in the same case:

The aloea, in combination with sulphate of quinone, acts energetically on the bowels; therefore the enemata are regulated according to their operation; a larger dose being given for the expulsion of the different species of ascariides; and the smaller doses for the prevention of their regeneration. The enemata already recommended should also be administered after the pills have been taken during two, three, or five days, the repeated exhibition of these latter rendering the former more efficient and generally successful.

201. G. The *Filaria Medinensis* (§§ 138—142.).

a. The prevention of this worm may be inferred from the causes and circumstances connected with its occurrence, namely, the endemic prevalence of filaria in certain climates and localities, its youngest brood living free in the water, or in wet grass, marshes, or moist soil, &c. Hence, wading through these places with naked feet, or exposing naked parts of the body to foul or impure water, should be avoided, as sources from whence the brood comes in contact with these parts, in the native countries of this enlarged, so that the infection of the filaria may occur, as shown by numerous facts, even in those tropical regions in which the worm is not endemic, an actual transfer from one person to another, or to dogs and horses, taking place. BRENNER says that, even in his time, the worm had become naturalised in Curacoa by the importation of negroes. No one, therefore, should use the same vessels employed by the patient in bathing, or washing the feet; and that great caution should be observed with the bandages of such patients.
WORMS — TREATMENT OF FILARIA MEDICINALIS AND ASCARIS LUMBRICIDES.

FICIAL, to be easily killed by poultices of boiled garlic. When quite superficial, an incision is made upon it, and the worm pulled out with a hook. Slave-dealers rub in civet and musk on its first appearance. But the worm often produces no annoyance for a long time, sometimes six to eight months. When it inflames and ulcerates the integuments over its seat, the part of which appears is seized, and carefully pulled and fastened to a roll of linen or stick, and gradually extracted by turning these twice daily. Some writers advise, when the worm is hard to cut away through the integuments, making an incision of several inches long, and removing the worm in a loop, or wedging into a piece of wood, and then pulling now on one side, and now on the other; the muscles being all the while relaxed. If inflammation, swelling, and pain are great, and the worm resists dragging, or break off, these symptoms are to be treated in the usual way, by poultices of linseed meal, or of onions and bread, or of onions boiled in milk, or of roasted onions, &c. In these cases, numerous means have been recommended in addition, but none of them appear very appropriate or successful.

203. From the most ancient periods, the breaking of the worm has been considered a very serious accident; and severe inflammation, fever, gangrene, &c., have been, even by some modern writers, said to have resulted from it. According to the observations of most authors, who had themselves suffered from the breaking of the worms, violent swelling, inflammation, fever, sleeplessness had occurred, and were cured only when they were killed. The diagnosis, in cases of Filaria Medicinalis, should always be correctly made, in order to determine the presence of this worm, and to distinguish between F. rectal (see that article) and inflammatory swellings caused by it.

204. H. The Treatment of Ascaris lumbricoides (§§ 144—149.) — a. FOR THE PREVENTION OF THIS WORM, it is necessary to bear in mind the circumstances in which the eggs may occur, and the long period during which they may be preserved. Ricketts recommended that three English spelling bees should be kept for some time, and that they attain their full maturity, and undergo the process of segmentation in this situation. BARNY, BISCHOFF, and others have shown that alkalis and salts do not prevent this process. VERLOORN, that a period of eleven or twelve months is required for the completion of this process in the Ascaris lumbricoides. RIECHTEr and KÜCHENMEYER state that eggs which had been put in water had not shown any appearance of embryos several months afterwards. As to what becomes of the ready-formed embryos, nothing is known positively; they probably get into our bodies with water, and perhaps this is sufficient for their development.

205. b. THE CURE OF ASCARIS LUMBRICOIDES. The number of medicines recommended with this object are so great that the judgment is distracted respecting them. In order to assist the selection, it has been attempted to determine the effects of the most used vermifuges upon living intestinal worms from recently killed domestic animals, by REDI, ANDREY, LIEBLER, TOTTI, ARNEMANN, CHARRIER, and others. More lately, KÜCHENMEYER has had recourse to similar experiments made in the temperature of the animal, by mixing the anthelmintic in white of egg, and placing the living worm in the mixture; and has given us the following results, arranged according to the time in which roundworms died in white of egg mixed with the various remedies:

206. " 1. Death took place in one to two hours, white of egg mixed with creosote, and large doses of common salt, and corrosive sublimate.

207. " 2. Death took place in two to five hours, white of egg mixed with petroleum, cajuput oil, oil of turpentine, mustard, weaker solutions of common salt, and washed herring's milieu.

208. " 3. Death took place in five to fifteen hours, white of egg mixed with garlic, onions, laurel, cloves, wood vinegar, rad. pun. granati, tinct. gallasum, concent. sol. of sulph. soda.

209. " 4. Death took place in fifteen to twenty-four hours, white of egg mixed with camphor, anise, and infusions or decoctions of ginger, gentian, elm-bark, kousso, and hops.

210. " 5. Death took place after twenty-four hours, white of egg mixed with infusion or decoction of parsley, rice, milfoil, tansy, valerian, chamomile, wormwood, myrrah, quassia, calamus, ippacu- anna, walnuts, chios-bark, willow-bark, myrrh, catechu, kine, assafodilis, gum ammoniac, Peruvian balsam, ol. ricini, aqua picis, creosote water, &c.

211. This writer states that besides the remedies here enumerated, he has tested the semina cina (santonici) with their preparations. In a mixture of white of egg with coarsely powdered seeds, the worms live for days; and in a mixture of white of egg with a strong infusion of semin. cina, with repeated additions of unboiled powder, they also lived for days. In a mixture of santonies with water and white of egg, the worms lived for days; and also in white of egg with santonine and a little vinegar. At the same time, however, the total insolubility of the santonine was proved by further experiments. In white of eggs mixed with caster oil and santonine, the worms died within an hour; but in this experiment the temperature was raised too high. In a mixture of white of egg with nutrient santoniacum (santonica of soda) dissolved in water, ascariodes lived more than twelve hours. These experiments form an introduction to the treatment advised for Ascaris lumbricoides by KÜCHENMEYER, and more especially to the use of the preparations of santonine; but he previously notices the employment of the semina santonies by other helminthologists, who generally prescribed this remedy in the form of an electuary.

212. (a.) STORCK's FORMULA:—

One teaspoonful every three hours.

213. (b.) SELLE's TOXIC WORM ELECTUARY:—

One teaspoonful three times a day. This electuary is to be preferred some time after the expulsion of Ascarides, and to ascertain their permanent removal.

214. (c.) HOFFELD's WORM ELECTUARY:—

WORMS — TREATMENT OF ASCARIS LUMBRICOIDES — AFTER-TREATMENT OF.

Valeriana, 3 j. i. — Oxymel. Scillae, 3 j. i. — Syrupi Simp. q. s. ut flat electuarium molle.

One tea-spoonful every two or three hours.

215. (d.) C I ARUS and other German physicians advised the Seminum Santonici, coarsely powdered, to be sprinkled over bread, and spreading syrup or honey over the powder, administering from 5 ss. to 8 j. several times a day; but this appears to be only a temporary inconvenience, which soon disappears after the discontinuance of the remedy. This writer adds that “it follows, as a matter of course, to be cautious in the use of santonicum, that he would never give more than eight grains of it in two days, divided into doses of two grains each twice a day, and that, on the second day of its use, he would administer an aperient.”

216. (e.) BREMNER’S ELECTUARY —

A tea-spoonful to be taken twice or three times a day. After taking two tea-spoonfuls daily, for three or four days, alime and worms pass off with more copious stools. If the worms are not expelled, BREMNER administers some more of the electuary twice or thrice. If the first pot of electuary be insufficient, a second is taken, but watery stools must not be produced. He never allowed more than two potfials to be taken; and he considered it unimportant whether worms passed or did not pass during its use. To relax the bowels once in the midst of this treatment he prescribed the following:

Half a powder to be taken every half, or every hour, or two hours, until it operates. For leucorrhoea in the little objects he often gave CUBBINS’s oil (composed chiefly of turpentine rendered still more nauseous) in doses of two teaspoonfuls in water night and morning.

217. The Seminum Santonicum, KÜCHENMEISTER states, have been recently displaced by the preparations obtained from them, and in his opinion with justice. He extols chiefly two of them, viz. Santonine and the Santonate of Soda; all the rest being unnecessary. He considers it to be preferable to administer Santonine with fatty oils, in order to bring it into solution as readily as possible; and for this purpose he prefers to give it sprinkled upon bread and butter, or in the white of an egg with sugar; and afterwards to follow it every three or four days with a gentle purgative (jalap or confection of senna), or to administer it in castor oil — gr. iij. to iv. of the santonine* in 3 j. of the oil, to be taken in teaspoonfuls until purgative action commences. In this way the remedy should be repeated, if possible, for some days, or every other day, so that soft stools, rather than actual purging, should be passed. Milk and butter-milk may be taken during this treatment. “Amongst the santonine lozenges, those prepared from coccus, under the title of ‘the most deserving praise.’ KÜCHENMEISTER remarks that the most troublesome effects of this remedy are spasms, obstructions, with tenesmus, and even bloody stools; but that

* The preparation of santonine is best effected by the employment of anaminta. It must be tasteless, when pure, because it does not dissolve in the mouth. Dissolved in hot water, it is sparingly soluble; but is readily in oils. It is isodorus, has a slight acid reaction, continues reddish with alkali, and becomes yellow in the light of the sun. When pure, it still contains resin and essential oils, and is ever-smelling nauseous to the taste. — (Callow, in Pharmaco. Centrifact, 1849, p. 413.) and J. CLARUS, in Handbuch der speziellen Arzneimittelther., 1852, p. 383.)

with a careful employment of the remedy (gr. iij. to iv. with 3j. of castor oil) he has never seen ill effects produced by it, the administration of it with castor oil always preventing intestinal obstructions. The most annoying symptom, to the patient only, is the yellow or blue, or even green, appearance of objects, owing probably to the effect of this remedy on the nervous system; but this appears to be only a temporary inconvenience, which soon disappears after the discontinuance of the remedy. This writer adds that “it follows, as a matter of course, to be cautious in the use of santonicum, that he would never give more than eight grains of it in two days, divided into doses of two grains each twice a day, and that, on the second day of its use, he would administer an aperient.”

218. (f.) 1he Santonate of Soda.— Natron Santonicium has recently been greatly praised by H. E. RICHTER and KÜCHENMEISTER, for its successful action in cases of Ascaris lumbricoides. The latter of these physicians states that he has never seen injurious effects from this medicine, even when administered in doses of eight to ten grains twice a day to adults. “The remedy to be given alone, as every acid decomposes it, and it must not be mixed in electuaries.” He adopts nearly the following mixture: — He lets children (or adults) take a powder of santonate of soda with sugar (from two to six gramine) on a Friday night, and he repeats the same dose on Saturday morning (fasting) and evening, and again on Sunday morning. On Sunday, half an hour or an hour after the last powder, an aperient electuary (confectio senae, &c.), or a sufficient dose of jalap, is taken, so that several soft motions may follow. By these means the worms usually pass off alive; or they wander forth singly afterwards, and without stools, their residence having become disagreeable to them, Dr. POCKELS, who noticed a blackish discoloration of the tongue after santonine, praises, as a remedy for Ascaris lumbricoides, the root of Apium vite mar in conjunction with purgatives.  

219. (g.) I have found no remedies more efficacious for the Ascaris lumbricoides than turpentine as prescribed above (§§ 165—165.) and in Form, 216, and the infusion of apisidae and Santonics, as directed in Form, 216, in the Appendix. For this worm, also, as well as for the Oxyuris vermicularis, the preparations of the santonine, prescribed in the Appendix, will also be found successful. (See Formule 71, 80, 105, and 106.) These and other medicines will be frequently as successful without, as with, the preliminary treatment recommended by the German writers; the exact operation of such treatment often being not very manifest. The great success derived from the powder and tincture of hamula, in India, in the treatment of tape-worms (see §§ 190—192), and the effects of this substance upon these worms, promise similar results from it, if it were prescribed against the Ascaris lumbricoides and the Oxyuris vermicularis.  

220. iv. AFTER-TREATMENT OF WORMS.— It is often requisite after the expulsion of intestinal worms has been effected — 1st, To soothe the irritation, and to subdue the inflammation occasioned by the vermiform and drastic purges which had been produced. 2nd, To remove any stray worms which had become so sickened, or so injured by the treatment, as to be readily thrown off by motion.
which would restore the vital tone of the bowels and further injure the worms, and render their residence disagreeable or untenable. And 3d, to prevent the regeneration of these parasites by removing their ova and rendering the digestive mucous surface aseptic to their development. (c.) The purgative parts are those of high. I have thus best accomplished by emetics and cathartics, and by the use of iron, antimony, and the acetum of myrrh, camphor, aloes, and the nux vomica. Camphor may be cojnioned with iron or antimony, but the nux vomica, camphor, and aloes, are not to be taken together.

221. (b.) The second intention presupposes either the non-existence or the removal of those conditions against which the first intention was directed, and consists in the occasional exhibition of a moderate or less irritating dose or doses of the anthelmintic suitable to the expulsion of the worm found to be present, and the combination of it with such other means as are best calculated for the case. A single dose may be sufficient to effect this purpose, or several doses may be necessary. In the latter case, the dose should be increased gradually, the patient being kept under observation, and the dose increased until the worms are expelled.

222. (c.) The third intention is of no small importance if the permanent cure of the patient is desired. For the original conformation, or the depression of vital power, of the patient; or the irritability and exhaustion of the digestive canal, may be so great as to require the aid of the intestines to expel them, that a tonic and restorative treatment becomes imperative in order to prevent various unpleasant contingencies. Besides, in many instances, an ama has become so considerable as to require a treatment directed more or less to it, and to the other morbid tendencies. In these circumstances not only should due care be directed to the prevention of intestinal worms, but recourse should be had to those medicines which are calculated to restore the vital tone of the digestive organs, to improve the state of the secretions and excretions of the body generally, but of the intestines in particular, to promote the functions and actions of the bowels, and to render the human intestinal canal an unsuitable and ungenial habitation for the ova of worms and for their development. These are objects which should always be entertained after the expulsion of worms of whatever species, and should be attempted by such means as are most likely to accomplish them. It may be asked, however, where are we to find, how are we to combine these means, and how are we to prevent the patient to persevere in their use, or even to have recourse to them when he believes himself free from his enemy? I cannot say that there are no other measures calculated to attain these objects, but I may enumerate those which I have employed with these views, combining them variously, and exhibiting them in such successions, intervals, &c., and as the circumstances of particular cases appeared to require. The medicines which I have employed are iron, sulphate of iron, and purgatives, and the compost mixture of iron may be given with the decoction or infusion of aloes, &c.; or the sulphate of iron may be prescribed with sulphate of quina, compound galbannum pill, with the aloes and myrrh pill. Camphor may be cojnioned with these latter substances (§ 198.) singly or in the combination now stated. The sulphate of quina may be given with dilute sulphuric acid, and sulphure ash. The infusions of the barks may be taken with tonic and laxative tinctures, or with the mineral acids, &c., and laxative electuaries may be conjoined with sulphur, or antispasmodics, aromatics, or spices.

223. It is obvious that the diet of patients who have suffered from worms should be nutritious, digestible, and restorative; whilst it ought not to be too rich or full, or calculated to produce constipation, phlegm, or local congestions, as of the liver, &c. The regimen ought to be regulated so that sufficient exercise may be taken in the open air, and that all causes of debility and exhaustion should be avoided. The remarks already offered for the prevention of the human enterotoxæ (§ 157, et seq.) are equally necessary to the prevention of their return after their expulsion.
The term *zymotic* has recently been applied by Dr. Farr to *epidemic, endemic, infectious, and contagious diseases*, and has comprised small-pox, measles, scarlatina, hooping-cough, croup, thrush, diarrhœa, dysentery, cholera, influenza, ague, remittent fever, typhus, erysipelas, syphilis, hydrophobia. Viewing the Greek term to mean a *fever* by which the organic nervous system, or the vascular system and blood, may be infected or contaminated, either successively, or contemporaneously, or nearly so, the term well designates an extensive class of diseases, although its application implies an hypothesis; but it is well suited to the arrangement adopted by Dr. Farr in his admirable Annual Reports of Deaths, &c., in England (which see).
SUPPLEMENT.

SUPRA-RENAL BODIES.—SYNON.—Glandulae ad Plexum, Glandulae ad Plexum Nervinum, T. Wharton; Glandulae supra-renales, Renes Succenturiati, Aust.; Supra-renal glands, Supra-renal capsules, &c.

1. I. STRUCTURE AND FUNCTIONS.—In the present state of our knowledge the name “supra-renal bodies,” or that adopted by Wharton, appears more correct than supra-renal glands, the functions of glands not having been proved in respect of them; and the term, capsules, is equally inapplicable, even to their more external structure. Succenturiat, or reserved kidneys or bodies, are not less appropriate. The earliest notice of the connections and nature of these bodies appear to have been taken by Wharton, who pointed out their relations to the ganglial nerves, as remarked by Dr. Gull. Nevertheless the functions and diseases of these bodies received no attention from physiologists and pathologists (although in several instances, organic lesions observed in them had been published in the Epistomus Nature Curiosorum, and more recently by Vetter and Baille), until very lately, when the structure and functions of these bodies were remarked upon by Nagel, Berhmann, Eckel, Kolliker, Leydig, and Grey; and their diseases, especially in connection with a bronzed discoloration of the skin, were first investigated by Dr. Addison, and subsequently by Mr. Hutchison and others. It is chiefly, however, to Dr. Addison that the distinction of having first directed attention to these lesions is due. Although several cases have been recently observed and recorded — not always, however, with due care and precision — still the number of those in which a bronzed state of skin appeared more or less intimately connected with, and most probably caused by, disease of these bodies, is so great as to induce a presumption that the former appearance exists the latter lesion will be found. In order, however, to form correct views as to the phenomena by which diseases of the supra-bodies are indicated, as well as to the nature and consequences of such disease, it becomes requisite that we should previously briefly inquire into what is known of the structure and functions of these bodies. Unfortunately opinions on these topics have been, and, notwithstanding the frequency of microscopic research in modern times respecting them, still continues to be, very unsatisfactory.

Dr. Wharton, about the middle of the seventeenth century first noticed their connections with the ganglia of the solar plexus, and suggested a name for them, which appears more appropriate than any other which has more recently been given them.

2. i. STRUCTURE.—Kolliker has very recently described the microscopic appearances of these bodies, and noticed what appears to be their functions, and Dr. Harley has still more recently examined their structure. — A. The cortical structure of these bodies is described by the latter observer, as consisting of cells, arranged in irregularly-sized rows, in a fibro-vascular matrix, the rows of cells appearing like a number of dark yellow columns placed perpendicularly to the surface. The cells, when examined individually, seem to be composed of a homogeneous cell-wall, filled with granules, pigment, and some fat globules. Each cell has a well-marked nucleus, although not always visible. The cells are arranged in a number of larger and smaller masses, which are placed in regular rows, and thus give rise to the columnar appearance. In some cases, a column is composed of several cell-masses of different lengths, placed end to end; in others it consists almost entirely of one long cell-mass. Each column, as well as each cell-mass, is separated from the others by perfectly fibrous tissue, in which are included the vessels and nerves. Sometimes the cell-masses present the appearance of long tubes, enclosing a single straight row of quadrilateral cells. Each cell-mass is closed at the extremities, and is surrounded by a delicate homogeneous membrane.

3. B. The medullary substance, according to Kolliker, also has a stroma of connective tissue, which, prolonged from the cortical lamella, pervades the whole interior, for the most part, in more delicate fasciculi, constituting a net-work with narrow, rounded meshes. In this network lies a pale, fine-granular substance in which, in man, and in recent preparations, pale cells of 0.006—0.16" are generally observed. These pale cells occasionally present, in their fine-granular contents, a few fat, or pigment granules; their frequently very distinct nucleus with large nucleoli, their angular form, and occasionally their single or multiple, or even branched processes, resembling the nerve-cells of the central organs, although they cannot definitively be declared to be such. Dr. Harley states that the dark slate-coloured medullary substance is composed of a network of fibres, in the meshes of which are a number of large nucleated cells, which...
have been described by various writers as ganglion corpuses; but he thinks that these, like the cells in the cortical substance, are true secreting cells. This great difference of opinion (so frequently observed amongst microscopists) — the same nucleus being formed in the different organs by some observers, and as true secreting cells by others — prevents in the present state of our knowledge much reliance to be placed upon the results of microscopic researches, each successive observer being liable to the distrust which attaches itself to his predecessors. However the following is less liable to objection: —

4. C. The nerves of the supra-renal bodies are, according to Bergmann and Kölliker, extremely numerous; arising, according to them, from the semilunar ganglion and renal plexus, and to a small extent from the vagus and phrenic nerves; but most probably intercommunicating with, rather than arising from, the latter. In man, Kölliker counted in the right supra-renal body thirty-three trunks, eight of which were $\frac{1}{4}$ of an inch in diameter; seven of $\frac{2}{3}$ of an inch; and thirteen of $\frac{2}{3}$ of an inch; and found that without exception, or at all events in a very beautiful proportion, they were constituted of dark-bordered, finer and medium-sized, or even thick fibres; were whitish or white, and furished with isolated larger or smaller ganglia. They are especially apparent on the inferior half and inner border of the organ, and appear to be all destined for the medullary substance, in which, at least in the Mammalia, an extremely rich plexus of dark-bordered, finer fibres occurs, inclosed in the trabecula and connective tissue, their terminations, however, being nowhere perceptible.

5. ii. Functions. — As regards the functions of the supra-renal gland, the absence of all physiological indications, and so long as the course of the nerves in them is not more accurately known than at present, only very general observations can be offered. Kölliker considers the cortical and medullary substances as physiologically distinct, and that the former may, provisionally, be placed with the secretory organs; the function of secretion assigned to it; whilst the latter, on account of its extremely abundant supply of nerves, must be regarded as an apparatus appertaining to the nervous system, in which the cellular elements and the nervous plexus either exert the same reciprocal action as they do in the grey nerve-substance, or stand in a relation as yet wholly uncertain towards each other.

6. According to Leydig, the cortical substance of the supra-renal capsule of the Mammalia corresponds to the yellow, granular, and striped supra-renal bodies of fishes and amphibia; whilst the medullary substance of the mammalian organ, which is abundantly supplied with nerves and cells, very like the ganglion-globules, represents the other divisions of the sympathetic ganglia: whence he concludes that Bergmann's view, according to which the supra-renal capsule are closely related to the nervous system, is undoubtedly correct, and this in accordance with the same relation to the ganglia of the sympathetic nerves, as the pituitary body bears towards the brain. Besides this relation to the nervous system, however, they have an intimate one with the vascular; and are, therefore, always pervaded by a very close capillary plexus.

7. The functions of the supra-renal bodies have been experimentally investigated by Brown-Sequard, Harley, and others, but with different results. We know how uncertain these results are in the lower animals, and the amount of confidence which may be reposed in them, not only in those which were obtained forty years since in order to determine the functions of distinct portions of the nervous system, but also in those more recently made with these and with other views. The former of the experimenters just named removed the supra-renal bodies from fifty-one rabbits, eleven adult cats and dogs, eleven young dogs and cats, eleven adult Guinea-pigs, four young Guinea-pigs, and two mice; and he states that the adult animals operated on died, on an average, in twelve hours, while the young or new-born animals lived thirty hours. From these experiments Dr. Brown-Sequard concludes that the supra-renal bodies are more necessary to life than even the kidneys; for animals will live two, or even three days, after the removal of the latter organs. Dr. Harley quotes from a later publication of Dr. Brown, in which the latter states, that of ten rabbits from which he extirpated the supra-renal capsules, six died, between the seventh and tenth hour, and four between the tenth and fourteenth hour after the operation, and adds, that the animals died too quickly to admit of their death being the result of peritonitis; and further, that the extirpation of these capsules is followed by symptoms which do not occur after injuries of the peritoneum or liver, &c., these symptoms indicating that the supra-renal bodies have an important influence on the blood, and that their nerves have a singular power upon certain parts of the central nervous system. He states that this latter influence manifests itself very distinctly sometimes cases after the extirpation or the puncture of one of these bodies, the animals being sometimes seized a few minutes before death by vertigo and rolling over. Dr. Brown-Sequard concludes, first, that if these organs are not essential to life, they are at least of very great importance. Secondly, that their functions appear to be at least as important, and a relative kidney in which they are absent, death in general supervenes more rapidly than after the removal of the kidneys.

(Original text of 1867, p. 374.)

8. Dr. Harley has published experiments which furnish different results from those now stated; and from these he infers, that "the supra-renal capsules are not absolutely essential to life," that "the removal of the right, is generally more fatal than the removal of the left capsule;" that "convulsions do not necessarily follow the removal of the capsules;" that, "when death follows upon the extirpation of the supra-renal bodies, it is in most cases in consequence of the injury done to the neighbouring tissues; perhaps more frequently the maturation of the ganglionic system of nerves;" that "absence of the function of the supra-renal bodies is not proved to have any special effect in arresting the transformation of hematin, or in increasing the formation of blood;" and that the suppression of the functions of these bodies is not attended by an increased deposit of pigment in the skin, or its appendages, in certain of the lower animals; the problem of the connection of browned skin and supra-renal capsular disease, being more likely to be solved in the dead-house than in the physiological laboratory.
9. Viewing the structure and connections of the supra-renal bodies as altogether similar to those of the pituitary gland, and considering these organs as very intimately connected, anatomically and functionally, with the ganglia and ganglionic plexuses, I have been induced to view them as organs contributing or subsidiary to the organic nervous force or influence exerted by the ganglionic nervous system. Thirty-four years ago I published this opinion in my Physiological Notes, &c. (in 1824), and stated that this gland reinforced the ganglionic nervous influence, endowing the brain by means of the ganglionic nerves distributed to the cerebral organs; that it was a portion of the ganglionic nervous system contributing to the nourishment and functions of the brain, and imparting an unity of development, of permanent nutrition and of function, to the double organs composing the cerebral mass. It appears very probable that similar offices are performed by the supra-renal bodies as regards the ganglia and ganglionic plexuses of the abdomen; these bodies contributing to the functions of the organic nervous or ganglionic system, as displayed by the abdominal organs — whether digestive, assimilative, or generative. That both the pituitary body and the supra-renal bodies perform these important functions — important not only as regards the performance of their respective functions, but also as regards the life of the individual — appears to be manifest from the nature and character of the nervous communications existing between them and other parts of the ganglionic nervous system; for, instead of describing these communications merely as branches of nerves detached from other ganglia or parts, it would be more correct, taking the size and appearance of these branches into consideration, to describe them as branches sent from the medullary structure of these bodies, to those ganglia, plexuses, and nervous trunks, in order to convey to these the special influences or functions of these bodies; or, otherwise, to reinforce and combine the influence exerted by these several ganglia and parts, with which they are anatomically connected. That these bodies are of the greatest vital as well as functional importance is evinced not only by the consequences following their structural lesions, and by the presumed nature of their functions, but also by the manner and the positions of their lodgements; both the pituitary and the supra-renal bodies being so located as to render them, in their respective situations, further removed, and better protected from injury, and even from structural or other disease, than any other part of the animal organisation.

10. II. Structural Disease of the Supra-renal Bodies. — Lesions of the Supra-renal Bodies, and their Associations, &c.

Classification. — IV. Class I. Order (See Preface, &c.).

11. Definition. — General languor and debility, anaemia, feebleness, languor, and slight depression of the general vigour of the body; irritability of the stomach, frequent vomiting, and pain in the back and loins, often with a bronzed or dusky hue of the general surface, rapidly increasing exhaustion, emaciation, &c.

13. Disease of the supra-renal bodies usually commences so gradually as not to admit of the patient's knowing the moment at which he first began to experience loss of health or strength. It is almost always gradual in its early progress, although often rapid in its more advanced course. The slowness or rapidity of its progress must, on the present state of our knowledge, be attributed to the nature and extent of the organic lesion, to the circumstances of one or both bodies being affected, and to the nature and severity, local or constitutional, of the malady with which structural change of these bodies is complicated.

13. Symptoms. — Generally the patient at first complains of weakness and languor, and of indisposition to bodily and mental exertion. The appetite is impaired or lost; the pulse is slow, weak, and often frequent; the whites of the eyes are pearly; the body is sometimes more or less emaciated, or, if not emaciated, leuco-plagiomatic or cachectic, or discoloured, and generally anemic. Uneasiness or pain, often severe, is referred to the region of the stomach, epigastrum, back, or loins. Nausea, sickness, retchings, and frequent vomitings often occur, especially as the prostration, anaemia, and discoloration of the skin advance. In some cases, complicated with disease of other organic organs; in others, in which the disease is acute or disorganising, the discoloration may either be absent or overlooked. In other cases, it is slight, or in patches, consisting of a murky hue; but, in others, it amounts to a bronzed tint, and is general over the whole surface, but is commonly most marked on the face, neck, superior extremities, penis, and seromun, in the fixtures of the axille and limbs, around the umbilicus, &c., varying in depthness from a dingy or smoky appearance to a chestnut-brown, or colour of a muttato. In some cases, patches of a lighter hue occur in various parts; and in many the discoloration may be remarked in some of the internal surfaces, the peritoneum, pleura, &c.

14. With the continuance and progress of disease, the languor, anaemia, loss of appetite, and feebleness of the heart's action are aggravated. The discoloration of skin becomes in some cases more marked, the commissures of the lips much darker, the pulse smaller and weaker, vomiting more frequent and urgent, and pain and weakness of the back and loins more complained of. At last the patient sinks and expires, after a period which is very indefinite, so that the disease may appear almost acute in some instances, and more or less chronic in others, most probably owing either to the severity of the disorganising lesions affecting the supra-renal bodies, or to the nature of the complications characterising particular cases.

15. Although lesions of these bodies are often uncomplicated with disease of any other organ, although no lesion or disorder of any important or vital part can be detected, in many cases, during the life of the patient, lesions of these bodies, and a peculiar anaemia, being the only or chief lesions found after death, very frequently accompanied with discoloration — yet they are often associated with other diseases, remarkable, in general, of a constitutional, chronic, or cachectic nature, more especially with general or partial tuberculosis, with cancer, and with disease of the lungs, &c.

16. The following table of cases of disease of the Supra-renal Bodies comprises nearly all those which have been published up to this time. It is constructed according to the method of Mr. Hutchinson; and to it I have added some recent cases.

Renal Bodies and of Bronzed Skin.

**General Symptoms, Complications, &c.**

<table>
<thead>
<tr>
<th>Duration of Disease</th>
<th>Mode of Death</th>
<th>Insufficiency After Death</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 years</td>
<td>Acute pericarditis and pneumonia.</td>
<td>Supra-renal bodies both remarkably insufflated and as large as eggs, and quite disorganised; recent pericarditis and pneumonitis; no tubercles, nor other visceral disease.</td>
<td>A well-marked case. No chronic lesions but those of supra-renal bodies.</td>
</tr>
<tr>
<td>6 months</td>
<td>Not stated</td>
<td>Both supra-renal bodies considerably distended and contained compact fibrous concretions; gastric mucous surface inflamed; no tubercles; no other visceral disease.</td>
<td>The deposits in supra-renal bodies resembled tubercles, but there was no tubercle in other organs.</td>
</tr>
<tr>
<td>7 months</td>
<td>Passed into a torpid state.</td>
<td>Supra-renal bodies completely destroyed and converted into stromous deposits; lungs absorbed and carried by the venous vessels; tubercles in lungs; spleen enlarged.</td>
<td>The blood, both before and after death, contained a great excess of white corpuscles.</td>
</tr>
<tr>
<td>Several months</td>
<td>From collapse and sinking.</td>
<td>Supra-renal bodies wasted and destroyed, both weighing only 15 to 18 grains. No other disease.</td>
<td>The disease of supra-renal bodies was an atrophy; probably consequent on inflammation.</td>
</tr>
<tr>
<td>1 year</td>
<td>Speedy sinking</td>
<td>Both supra-renal bodies greatly enlarged, of irregular surface, and much inflamed; internal structure lost; nucleated cells. No other important disease.</td>
<td>This case was recorded by Dr. Bright before the importance of detection of supra-renal bodies was recognised.</td>
</tr>
<tr>
<td>4 months</td>
<td>Died of exhaustion in three days after admission.</td>
<td>Both supra-renal bodies contained much necro-inflammatory deposit; throughout their structure.</td>
<td>Foetidity had been so urgent in this case as to suggest the existence of malignant disease of the stomach.</td>
</tr>
<tr>
<td>5 months</td>
<td>Sunk gradually</td>
<td>Tubercular deposit in one supra-renal body; in the spleen also, and the kidneys were degenerate.</td>
<td>The extent of discoloration of skin was proportioned to that of disease of supra-renal body, one being a sound.</td>
</tr>
<tr>
<td>5 months</td>
<td>Not stated</td>
<td>Died from cancer.</td>
<td>The degree of bronzing appears to have been proportioned to that of disease of supra-renal body, one only being affected.</td>
</tr>
<tr>
<td>8 months</td>
<td>Died from exhaustion consequent upon a purgative.</td>
<td>Both supra-renal bodies enlarged to the size of half a kidney; their structure converted into a firm tubercular-like matter, and in parts softened.</td>
<td>The disease of bronzing was slight; the disease of one supra-renal body being recent.</td>
</tr>
<tr>
<td>1 year</td>
<td>Sudden exhaustion</td>
<td>Both supra-renal bodies atrophied and destroyed; the left contained cyste, the right solid concretions.</td>
<td>One supra-renal body was affected, and the bronzing was slight.</td>
</tr>
<tr>
<td>Unknown</td>
<td>Died from exhaustion caused by a short journey.</td>
<td>Both supra-renal bodies completely atrophied, and contained calcareous concretions; emphysema of lungs; faulty degeneration of heart.</td>
<td>The chain of morbid phenomena was very complete in this case.</td>
</tr>
<tr>
<td>8 weeks</td>
<td>Collapse</td>
<td>Each supra-renal body enlarged to the size of a half a kidney; their structure converted into a firm tubercular-like matter, and in parts softened.</td>
<td>This appears to have been idiopathic disease of supra-renal bodies, no tubercles being found in other organs.</td>
</tr>
<tr>
<td>8 months</td>
<td>Diarrhoea, followed by succession of epileptic fits, vomitings, &amp;c.; died on fourth day of state.</td>
<td>Both supra-renal bodies destroyed, containing gritty, cheesy, and semi-purulent deposit. No other disease.</td>
<td>In this, as in case 23, a peculiar disagreeable body was exhaled from the patient for three or four weeks before death.</td>
</tr>
<tr>
<td>3 weeks or more</td>
<td>Sunk into a typhoid state, with low fever.</td>
<td>Both supra-renal bodies were converted into abscesses, but their cortical substance was not wholly destroyed; circumscribed abscesses in the liver.</td>
<td>In this case the suppuration and inflammation of supra-renal bodies had probably been acute and recent.</td>
</tr>
<tr>
<td>Not stated</td>
<td>Died of distemper in a melancholy state.</td>
<td>No inspection.</td>
<td>The cachexia was precisely that of diseased supra-renal bodies.</td>
</tr>
<tr>
<td>About 6 months</td>
<td>From exhaustion</td>
<td>No inspection.</td>
<td>The bronzed patches indicated the patient's speedy death when there were not other alarming symptoms.</td>
</tr>
</tbody>

17. Mr. Hutchinson has collected a number of the cases which have been recorded, and has given a view of the chief symptoms which have characterized them. I shall notice these symptoms briefly and in succession, but independently of his account of them. — 1st. Bronzing of the skin was observed in the majority of cases of structural lesion of the supra-renal capsules, recorded by Dr. Adnson and some others, and this physician was inclined to believe that this symptom was indicative of such lesion. Several cases have more recently been observed where lesions of these capsules have been found without this change of the colour of the skin, and without any change whatever. Several such instances are recorded in the 8th vol. of the Transactions of the Pathological Society. — 2d. Great debility, without any evidence of thoracic or organic disease, loss of mental energy, faintness, exhaustion, &c., were very general symptoms. — 3d. Irisability of the stomach, nausea, occasional or frequent vomiting, were also prominently observed. — 4th. Pains in the epigastrum, back, and loins, sometimes acute, in some instances dull, or an acheing merely, was general. — 5th. Anemia was also, generally present, this fluid being impoverished and abounding
with white corpuscles, the soft tissues being flabby.—
6th. Feebleness of the heart’s action; a soft, compressible, and more rarely a quick pulse were usually observed.—7th. A cachexia, febrile, phlegmatic, and unhealthy appearance of the body, with or without emaciation, were frequently remarked.—8th. A disagreeable and peculiar odor was exhaled from the body, in some cases, during life; and—9th. Several nervous and convulsive symptoms were observed in a few instances. The tongue, the bowels, and the urine, did not present much indication of disorder. Death appeared to result chiefly from vital depression or exhaustion, with more or less indications of alteration of the circulating fluids. In some cases, death was attributable to the disease with which the lesion of the supra-renal bodies was complicated, as to cancer, tubercular disease of the lungs, &c. The circumstances of one of those bodies only being diseased, and the extent to which the structure of one or both had been destroyed, may be viewed as modifying or altogether altering the symptoms and the final issue.

18. ii. The chief lesions of these bodies which have been recorded are the following:—
(a) Appearances of acute inflammation and excre-

Form. 160. Gargarismi Antisepticum.  
B. Decocto Cinchonae 3 xij.; Camphorae gr. x.; Aromatis Hydrochloratis gr. x. M.

Form. 161. Gargarismi Asthergesis.  
B. Infusus Kramerianus 3 xij.; Acidum Sulph. Dilutum 3 xij.; Syrupi Moris 3 xij. M. Flat Gargarismi. (For the laxation of the Urns and Feces.)

Form. 162. Gargarismi Asthergesis Zonellii.  

Form. 163. Gargarismi Bi-horatis Sodae.  
B. Bi-horatis Sodae 3 xij.; Aquae Rose 3 xij.; Mollis Despumati, Tinctura Myrrhae, 4 x. 3 ss. M.

Form. 164. Gargarismi Catechu Theriacum.  
B. Infusi Rose 3 xij.; Tinctura Catechi 3 xij.; Acidum Sulphurici Diluti 3 xij.; Tinctura Opii 3 xij. Sit Gargarismi sapio uterum. (A. T. THOMSON.)

Form. 165. Gargarismi Comune.  

Form. 166. Gargarismi Potassae Nitritae. (1)  
B. Potassae Nitritae 3 xij.; Mollis Despumati 3 xij.; Aquae Rose 3 xij. M. Flat Gargarismi.

Form. 167. Gargarismi Potassae Nitritae. (2)  
B. Potassae Nitritae 3 xij.; Decocto Hordei 3 xij.; Oxyellae Simplicia 3. M. (BRANDE.)

Form. 168. Guttae Acetatis Morphi.  
B. Morphiae Acetatis gr. xv. j.; Aquae Distillatae 3 xij.; Acidum Aciditi Dilutum 3 xij.; Tinct. Cardamomi. Comp. 3 ss. M.

Form. 169. GuttaeEtheris Terebinthinatis.  
B. Olei Terebinthis f. Ether. Sulphuridi. (vel Ether. Nitri. part. j.) M. (Nearly the same as that recommended by M. DURAND in Jambusal and Biliary Calculi.)

Form. 170. Guttae Anodyne.  
B. Morphiae Hydrochloratis gr. xv.; Aquae Distillatae 3 xij.; Tinct. Lavandului. Comp. 3 ss. M. (In doses of form. v. to xxx. drops.)

Form. 171. Guttae Antimoniaci.  

Form. 172. Guttae Contra Spasmis.  

Form. 173. Guttae Contra Spasmis. (Stolé.)  

Form. 175. Haustus Aciditi Nitriti et Opium.  
APPENDIX OF FORMULÆ. — HASTUÉS.

FORM. 176. HASTUÉS ACIDI NITRITI ET OPII.
R Acidi Nitrirt Diuti 3 sq.; Infusi Opist. 3 sq.; Infusi Calamine 3 sq.; Malle, Flatus Haustus, ter in die capiendus.

APPENDIX OF FORMULE.—INFUSEM.

Form. 233. Infusum Guaicimi Compositum.
B Guaicum Lini ras. 15.3.; Glycyrrhiza Radicis concuss. 3.3.; Alkaengi tetrandriae caul. 3.3.; Coriandri Semen concass. 3.3.; Liquorice Calculi Oxv. Infunde per tres dies, dixit, sed; in rem aequo seque uniusquis pro dose, et bis dies repetatur. (SPRAGUE.)

B Glycerina Hederacea, vel Hederae Herbae, 3.3.; Radicis Glycerini 3.3.; Acidi Hydrocyanici 3.3.; Syripi Albae officinalis 3.3.; M. Fiat Haustum, sexta vel octava, quodque hora sumens.

Form. 235. Infusum Juniperi.
B Juniperi Baccharis contusasmarum 3.3.; Aquae Ferventis 3.3.; Macera in vashe leviter clausa per horas duas, et cola; dein addit. Spiritus Juniperi Compositi 3.3.; et inaspira, pro re nata, Poteana Bitterratis 3.3.; (Dosis, fluidic, ib. ad iv. quartae quoties).

Form. 236. Infusum et Mistura Juniperi Compositi.
B Baccaris Juniperi contus, 3.3.; Seminum Ani i, cont., 3.3.; Seminum Foeniculi cont., 3.3.; Aquae Ferventis 3.3.; Macera per horas duas, et cola.

Form. 237. Infusum Lati.

Form. 238. Infusum Marmeli.
B Marrubii Herbae excis. 3.3.; Aquae Distillatoe Ferventis 3.3.; Macera per horas et cola, et cola.

Form. 239. Infusum Melissae Compositum.
B Melissae Officinalis, Radicis Glycerici, concuss. 3.3.; Seminum Ani cont., 3.3.; Seminum Foeniculi, Sem. Coriandri, cont., 3.3.; Aquae Buillentis 3.3. Infunde per horas et cola.

Form. 240. Infusum Menthe et Caryophylli.
B Folior. Menthae Viridi. Sie. 3.3.; Rose Gallice Petale. Sie. 3.3.; Caryophyllorum contus, 3.3.; Aurantii Cort. Sie. 3.3.; Aquae Ferventis 3.3.; Macera per horas et cola.

Form. 241. Infusum Menthe Compositum. (1.)

Form. 242. Infusum Menthe Compositum. (2.)
B Menthe Viridis excis. contusum 3.3.; Rose Gallicae Petalorum exsaccatus 3.3.; Aquae Ferventis 3.3.; Acidui Sulphuratus 3.3.; Barachii Pinelli 3.3.; Menthe et Rose Petals superinfundere Aquam cum Acidi dimidio mixtam. Macera; dein, Liquorem effundite, et Saccharum et Acidum roman. admen. (Dosis, fluidic, J. ad 0.5, bis ter, sequeator quoties).

Form. 243. Infusum Menthe et Thymii.
B Menthe Viridis Foliorum 3.3.; Zingiberis Radicis concass. 3.3.; Aquae Ferventis 3.3.; Macera in vashe leviter clausa per horas duas, et cola; in doses of 3.3. to 3.3., with Spirits (etheris Nitratus 3.3. 3.3. 3.) in Rheumatism, Arthritic Afections, and in Cachectic and Cynanotic Diseases.

Form. 244. Infusum Mullispoli Compositum.
B Herbae Mullispoli 3.3.; Herbae Rosmarinariae, Herbae Thymin Vulg., 3.3.; Semin. Coriandri, cont. 3.3.; Aquae Ferventis 3.3. Infunde per horam, et cola.

Form. 245. Infusum Pectorale.
B Herbae Matricarum, Herbae Rhamnus, Herbae Glycerici, 3.3.; Sem. Ani i, cont. 3.3.; Aquae Ferventis 3.3. Macera.

Form. 246. Infusum Pectorale. (2.)

Form. 266. Inusum et Mistura Tonic&apo; Arabinum. B. Semina Foliolum 3 ss.; Gentianae Radices concis. 3 ss.; Aurantii Cortici concis. 3 ss.; Limosae Cortici concis. 3 ss.; Semin. Coriand. Sat. contusm 3 ss.; Syrapi Papaveris 3 ss.; Aque Ferventis O. 12. Macera benes in vaso claustro, et colat. (Dosis, Cyathus Vinus singula miliaris, ejusque ventriculo. — In Lamiaceas. SPRAGUE.)

Form. 268. Inusum Valerianin. B. Valerianae Radices concis. 3 ss.; Aque Ferventis 3 ss. Macera in vaso leviser; et cola. Liquorem colat addo Tincturae Lavandulae Compositae, Syrapi Aurantiis, ad 3 ss. (Dosis, fluidam usq., ter quattuor quotid.);

Form. 270. Inusum Valerianae et Serpentinae Compos. B. Rad. Valerianae, Rad. Serpentinariae, Flor. Sambuci Nat. 3 ss.; Aque Ferventis 3 ss.; Macera per horas duas, et cola. Liquorem colat addo Aedifici Sulph. Arom. 3 ss.; Syrapi Papaveris 3 ss. M. (Fevera, Hysteric, et other Nervous Afecciones.)

Form. 271. Inusum Zingiberinis. B. Zingiberis Radices concis. 3 ss.; Aque Ferventis O. 12. Macera per horas duas in vaso leviser claustro, et cola. Tum addo Tincturae Zingiberis, Syrapi Cassiis, ad 3 ss. (Ehden is the best vehicle for giving the Liquor. Ferri Oxygennati, and it is also a very grateful aromatic in cases of Flatulency.)

Form. 276. Inusum Zinci Acetatis Compositis. B. Zinci Sulphatis, Plumbi Aceti, 3 ss.; Camphorm Comp. 3 ss.; Opil 3 ss. Solute in Aque Billemienti Oj. 

Form. 277. Inusum Indicum Jaculare. (Internally, in doses of from one grain to three, and externally in doses of 1/16 grain.) (Foe the best account of the preparations and uses of Indine, consult Dr. O’Shaughnessy’s translation of Logol on Sercol.)

Form. 278. Inusum Indicum Pernici. (Internally, in doses of from one half a grain to five grains; and externally. — Vide Ung. Ind. Plumbi.)

Form. 281. Inusum Lenticus Boracic. B. Catecl 3 ss.; Pulv. Traganthi Compos. 3 ss.; Syrapi Tolotan 3 ss.; Bilboritis Sodas 3 ss.; Confest. Rosee 5 ss.; Syrapi Althaeae 3 ss. Fiat Mist. de quo lambat paroxysmum sepulchro. (Sorae Tarvii, (Epithuspis.)

Form. 285. Inusum Demusculae. (2.) B. Catecl 3 ss.; Pulv. Traganthi Comp. 3 ss.; Syrapi Tolotan 3 ss.; Potassm Nitratis 3 ss.; Confest. Rosari 3 ss.; Syrapi Simp. q. s. ut fiat Lenticus, de quo lambat paroxysmum plus re nat.

Form. 287. Inusum Emilolini &e; Benefeci. B. Saponis Venet. 9 ss.; Sult in Olei Amygdal. Dulcis 3 ss.; Mannum Purificatis 3 ss.; Potassm Bitartr. 3 ss.; Syrapi Althaeae 3 ss. M. Fiat Lenticus.
APPENDIX OF FORMULE. — LINCTUS — LIQUOR.

Form. 298. Linctus Myrrhae et Ipecacuanhae.

Form. 299. Linctus Oedemer. (1.)

Form. 300. Linctus Oedemer. (2.)

Form. 301. Linctus Opilatis.

Form. 302. Linctus Opilatis cum Scilla.

Form. 303. Linctus Pectoralis.

Form. 304. Linctus Potaesi Nitratis.

Form. 305. Linctus Ammonii cum Oleo Terebinthini.
R Liquoris Ammonii 3 ss.; Olei Olivei 3 jj.; Olei Terebinthini 3 ss.; Olei Limoins 3 ss.; Agita sum donec nascantur.

Form. 306. Linctus Ammonii et Terebinthini Comp.

Form. 297. Linctum Anisynum. (1.)

Form. 298. Linctum Anisynum. (2.)
R Liquoris Saponis Comp. 3 j.; Liquoris Ammonii 3 iij.; Olei Caryophylli 3 j.; Tinctura Opilii 3 ss.; M. fiat Linctum.

Form. 299. Linctum Camphorae Fortis.

Form. 300. Linctum Camphorae Comp. (1.)

Form. 301. Linctum Ferrugineum.
R Antimonii Potass. Taurinatis gr. xxij.; solve in Aqua Destillat. 3 ij.; vel q. a.; deinde tene bened. cum Adips. Praepar. 3 iij.; et fiat Linctum. (The anthyrum is partially absorbed without producing any Phlogosis.)

Form. 302. Linctum Iodini.
R Liquoris Iodini 3 iij.; Iodini gr. viij.; vel x.; M. fiat Linctum.

Form. 303. Linctum Phosphoratum.

Form. 304. Linctum Pyrethri.
R Tinctura Pyrethri 3 vj.; Linctum Camphorae 3 ij.; Liquoris Ammonii 3 j.; M. fiat Linctum.

Form. 305. Linctum Rubefaciens.
R Camphorae 3 j.; Olei Olivei et Lq. Ammoni. 3 j.; Olei Maris 3 j.; Olei Micos. (Externum ad partes in deep-seated Infammation.)

Form. 306. Linctum Saponis et Camphorae Comp.

Form. 307. Linctum Contra Spasmos.
R Olei Olivei, Olei Terebinthini, Liquoris Ammonii, Tinct. Opil., Linctum Saponis Comp. 3 as.; Fiat Linctum.

Form. 308. Linctum Stimulans.

Form. 309. Linctum Sulphuri-Saponaceum.

Form. 310. Linctum Tabacii.
R Tabaci Folioli 3 j.; Aconitis Fornicans 3 jj.; Simul liquefaci et macerat proprie igitur donec tria illa ablot folia; tunce exprim. (Ph. Amst.)

Form. 311. Linctum Terrebenthini Comp.

Form. 312. Linctum Terrebinthino-Phosphoratum.
R Olei Terebenth. 3 j.; Camphorae raue 3 ij.; Linctum Ammon. Fort. 3 ij.; Sap. Medicinis. 3 j.; Phosphor. Per. gr. x.—xij.; pulvis solut. in Olei Calcati, vel in Olei Caryophylli 3 ij.; vel q. a.; M. (In Chronic Rheumatism and Epidemic cholera.)

Form. 313. Linctum Thebaliacum Compuestum.
R Opii Puriss. 3 jij.; Camphorae, Succinni, aë 3 ss.; Spirit. Vini 3 vj.; M. fiat Linctum.

Form. 314. Linctum Volatilis.
R Olei Olivei 3 ij.; Camphorae 3 iij.; Liquoris Ammonii 3 ij.; M. fiat Linctum.

Form. 315. Liquor Aethatitis Morphi.
R Morphes Aethatitis gr. xvij.; Aque Distillat. 3 vij.; Arboii Aethitis 3 ij.; Spirit. Pimentae 3 v.; Solve. (Dosis a HI n., ad III xx.)

Form. 316. Liquor Antimonii Potassio-Taurinis.
R Antimonii Potassio-Taurinis gr. xxxij.; Aque Distillat. 3 xiv.; Spiritus Rectificat. 3 ij.; Uvarum Passum, dextrum admiss. 3 ij.; Macera per hedera, et col. (Dosage of from 10 to 30 drops on Sugar, or in a suitable vehicle.)

R Balsami Ferraviani 3 j.; Olei Siccii, Olei Rosmarinis, Olei Caryophylli, Olei Pimentae, aë 3 ss.; Spirit. Vini Rectificat. 3 xas.; M. fiat bene. (In doses of from 10 to 30 drops on Sugar, or in a suitable vehicle.)

Form. 318. Liquor Bifloratus Sod. Comp.
R Bifloratus Sod. Potaeae Biflorat. 3 as.; Aque Destillat. 3 ij.; Pro infantibus; et 3 ss.—3 ij. ter die pro Adultibus.

Form. 319. Liquor Calcium Chloridii. (Becugas.)
R Acidis Hydrochloridis, Aque Destillati, aë 3 iv.; Maronis Albi Pulv. q. a. ad nutrimentum.
APPENDIX OF FORMULÆ. — LIQUEUR — MISTURA.

Form. 329. LIQUEUR CAMPHERE ET THEBEEUS.

Form. 321. LIQUEUR FERRI OXYGENATI. (Rendos.)
B. Ferri Sulphatis 3 ss.; Acid. Nitrillii Fortissimi (per pound) 3 joi. Tese prohib simul in mortatorio virro donec efficaci vestra una; dein addas gradatim Aquae Destillatae 3 joi. Postea per chartam cola. Dios a quatum ad decem gotas, ter quattuor, quotidib; in Quassia, vel Zingiberis, vel Carpyphylli, Infusionem. (In Worms, Harnorrhagias, &c.)

Form. 322. LIQUEUR HYDRAORGYI BICHLOIDI.
B. Hydargyrri Bichloridi gr. iv.; Acid. Hydrosolvisii gr. v.; Aquae Destillatae 5 joi.; Spirit. Temotorii 1 joi.; Tinctura Cordi 3 joi. Tese prohib simul in mortatorio virro ut fiat Soluto. Incip. somendo gr. vi. 15, norte unum ex harum Infusionem Linii, vel Decocti Glycyrrhiza, posteaque pro re natâ augaueris. (Safrae.)

Form. 323. LIQUEUR POTASSII IODIDI.
B. Potassii Iodidi gr. xxvi.; Aquae Destillatae 3 joi. Solve terendo in vaso virro. (Dosis M i. xvi. &c.)

Form. 324. LIQUEUR POTASSII IODIDI IODURESI.
B. Potassii Iodidi gr. xxv.; Iodium gr. s.; Aquae Destillatae 5 xvi.; Solve terendo in vaso virro. (In doses of 10 drops to 30, three times daily.)

Form. 325. LIQUEUR MORPHII CITRATI.
B. Morphi Puris gr. xv.; Acid. Citri Cristal. gr. viii.; Aquae Destillatae 5 joi.; Tinct. Coccii. i. Solve. (Dosis M i. xvi.)

Form. 326. LIQUEUR PLUMI ACETATI DILETUS.

Form. 327. LIQUEUR POTASSE CHLORATI.
B. Potassa Chloratis 5 joi.; Aquae Destillatae 3 xvi. (In indolent Sorres as a Lotion, and internally in three times its bulk of vehicle.)

Form. 328. LIQUEUR POTASSII IODIDI IODURESI CONCENTRATI. (Lancet.)
B. Iodidi 3 joi.; Potassii Iodidi 3 joi.; Aquae Destillatae 5 joi. Solve. (This solution contains one twenty-fourth part of Iodine. Dose for an Adult, six drops in sugared Water in the morning fasting, and six an hour before dinner; increasing the dose, every week, two drops, until it reaches to thirty or thirty-six daily.)

Form. 329. LIQUEUR POTASSII IODIDI IODURESI DILOSo.
B. Iodidi --; Potassii Iodidi --; Aquae Destillatae 5 joi. Solve. (Dosis No. 2. No. 3.)

Form. 330. LIQUEUR ZINCI ACETATI.

Form. 331. LIQUEUR HYDROXYCARCI.

Form. 332. LIQUEUR ANTIPHOTOSPICA.

Form. 333. LIQUEUR ANTIPOISICA.
B. Potassii Sulphurici 3 joi.; Aquae Oi.; Acid. Sulphurii 3 joi. Mische; flat Lotio, bis terce quotidie utenda. (Dupuytren.)

Form. 334. LIQUEUR BORACIA.

Form. 335. LIQUEUR AMOROUS.

Form. 336. LIQUEUR AVIPOIS.

Form. 337. LIQUEUR FLAVA.

Form. 338. LIQUEUR HYDRAORGYI CAMPHERATA.
B. Hydargyrri 3 joi.; Acid. Nitrillii 3 joi.; Aquae Destillatam adde, dem Campheare 3 ss. ad 5 lss. adde. (In Chronic Cutaneous Affections, applied twice daily.)

Form. 339. LIQUEUR SUBTITIS.
B. Acid. Hydroxyaceti 3 joi.; Mist. Amygdali. Amygd. 3 ss.; Hydrargyri Bichloridi gr. 0.1.; flat Lotio; ope spongii partibus affectu applicando.

Form. 340. LIQUEUR TERRERITHINAE ET CAMPHERAE.

Form. 341. LIQUEUR TERRERITHINAE.
B. Olei Terebenthi, Alcoholis, 5 ss. 3 joi.; Camphorae 3 joi. flat Lotio. (In Psiticia, &c.)

Form. 342. MISTURA ACETATI MORPHII.

Form. 343. MISTURA ACIDIS BORACICIS.

Form. 344. MISTURA ACIDIS HYDROXYCARCICIS.
B. Acid. Hydroxyaceti 3 joi.; Siropt. Isobutunni 3 joi.; M. flat Mistura, cujus caput Cochlearis unum amplum tertia vel quartâ quâque hora.

Form. 345. MISTURA ACIDIS HYDROXYCARCICIS.
B. Acid. Hydroxyaceti 3 joi.; Siropt. Isobutunni 3 joi.; M. flat Mistura, cujus caput Cochlearis unum amplum tertia vel quartâ quâque hora.

Form. 346. MISTURA ACIDIS NITRICI.
B. Extract. Hyocaciunctii 3 ss.; Acid. Nitrici Diluti 3 joi.; Aquae Distillatae 3 ss.; Siropt. Zingiberis 3 joi.; M. flat Mistura. (Dosis una; secundis horis, dumae paroxysmum.)

Form. 347. MISTURA ALKALAEI ANODINAE.
B. Tinctura Opii 1 joi.; Liquor. Potassae 3 ss.; Sphatikii Mysticatis 3 ss.; Aquae Purae 3 joi. Mische. (Dosis 1 joi. ad 3 joi. bis terce in die.)

Form. 348. MISTURA ALKALAEI CARDIACEA.

Form. 349. MISTURA ALKALAEI GUTTAEI.

Form. 350. MISTURA AMMONIAE COMposita.

Form. 351. MISTURA AMMONIAE COMposita.
B. Gumi Ammonii 3 joi.; Aquae Oxymelis 3 joi.; Vini Ipecacuanhae 3 ss.; Aquae Flor. Staphisangii 3 ss.; Spirit. Aquae Olii 3 joi.; M. flat Mistura, cujus caput Coelheare unum. (Chronic Pectoral Complaints.)
APPENDIX OF FORMULAE. — MISTERA. xiii

Form 359. MISTERA AMMONIUM HYDROCHLORATIS.
B Hydrochloratis Ammonii, Extr. Glycyrrh., à 3 j.; Decocti Altheae 3 j.; Oxymel, Simp. 3 j. (vel Oxymel, Scillae.) M. (Caustica Affectus.)

Form 358. MISTERA AMYGDALA.

Form 354. MISTERA AMYGDALA. — (Infantilis.)

APPENDIX OF FORMULÆ. — MISTURA.

FORM. 408. MISTURA FERRUGIA. (PETRON.)
M. Syrupi Papaveris 3. vij.

FORM. 409. MISTURA FERRUGIA NERVINA.
M. Syrup. M. Capit. cochlæa unum amplum tertii vel quartus horas.

FORM. 410. MISTURA GALIACI AMMONIACI.

FORM. 411. MISTURA UMBRAE HYGROPHYRI RICHLORIDÆ.
B Decoct. Glycyrrhizæ 3.; Aque Cynanum 3. l.; Liqueur Hydriphoriae Richloridiæ (FORM. 322); Syrupi Aurantii, 3. l.; Aque Fructus; M. Flat Mistura, cujus sumnat Coch. ampli.; M. Capit. 3. l.; statim post cillum, his tertiis in die.

FORM. 412. MISTURA EMESIS COMPARATE COMPOSITA.
B Cupraris Cortis incomp. 3. l.; Aurantii Fructus exsiccat. 63.; Aqua Aerantis Octarum. Mecora par horas quatuor in vaso classo, et colo.

FORM. 413. MISTURA EMESIS SALICIS COMPOSITA.
B Cot. Salici contus. 3. l.; Aqua 63. Decoque ad cæstacium j.; eis adea Carophylli contus. 3. el.; et colo.

FORM. 414. MISTURA INMISTUS SENECIO COMPOSITA.

FORM. 415. MISTURA INFUSUM SERPENTARIELAE COMPOSITA. (1.)

FORM. 416. MISTURA INFUSUM SERPENTARIELAE COMPOSITA. (2.)

FORM. 417. MISTURA INFUSUM UVRÆ URSI.

FORM. 418. MISTURA INFUSUM UVRÆ URSI COMPOSITA.
B Uvræ Ursi Fol. 3. l.; Radicis Rhei concis. et cont. 3.; Aque Fructus 3. l.; M. Seracera per horas 3. l.; in vaso classo, deinde colo.

FORM. 419. MISTURA LAXANS.

FORM. 420. MISTURA MUCILAGINIS ASOMYNAI.

FORM. 421. MISTURA MYRRHAE COMPOSITA.
B Myrrhis 3. l.; Decoct. Glycyrrhizae Fructus 3. v.; Simil. terre, et col.; Dosis 3.; hic ut vel prophanæ. Singulis doctis interdum adde, Sodae Carbonatis gr. xij.; vel Aq. Fructus 3. l.; vel Tincturae Comp. 3. l.; M. (In the latter stages of Phthisis Pulmonalis, when languor or debility is a very prominent symptom, the above mixture, combined according to circumstances, is an excellent medicine.)

FORM. 422. MISTURA NERVINA. (1.)

FORM. 423. MISTURA NERVINA. (2.)

FORM. 424. MISTURA OLEÆNSA.

FORM. 425. MISTURA PECTORALIS. (1.)

FORM. 426. MISTURA PECTORALIS. (2.)

FORM. 427. MISTURA PHOSPHORATÆ.

FORM. 428. MISTURA FURMANS. (1.)
B Infus. Senes Comp. 3. l.; Magnesiae Sulphatæ 3. l.; M. Aque Fructus Sativ. 3. l.; Tinct. Senes Comp. 3. l.; M. Sumnntur Cochlæa iv. primo mane, et repetatur post horas tres, si opus sit.

FORM. 429. MISTURA FURMANS. (2.)
B Fol. Sennes, Conserve Menthe Viridis (F. 40.); 3. l.; Sem. Coriand. 3. l.; Aque Fructus Sativ. 3. l.; M. Flat Mistura, capiat partem itam secundius horis, donec bened. suum el alveus, et pro re natat repetatur.

FORM. 430. MISTURA REFREGERIS.

FORM. 431. MISTURA RESOLVDÆNS.
B Aq. Fruid. 3. l.; Ricini 3. l.; Sodae Carbon; 3. l.; Tinct. Comp. 3. l.; M. (In Engorgements of Islands, &c.)

FORM. 432. MISTURA RHEI COMPONITA.
Form. 464. PIULAE ANTIMONII ALTERNAE.  
R Antimonii Oxyphururetij 3; Florum Subpur. 3; 
Saponis Composta 3; Extri. Coni. 4; Suspi. 
Athame s. q. i. in Pilulae xxv, quorum capiat 
ibi etque apud, ter quidem.

Form. 465. PIULAE ANTIMONII ET GUALCI COMPOSITA.  
R Antimonii Oxyphururetij 3; Florum Subpur. 3; 
Resinae Gualci, Extri. Coni. 4; Suspi. 
Athame s. q. i. in Pilulae xxv, quorum capiat 
binae utque per tres die.

Form. 466. PIULAE ANTIMONII ET RUSSI COMPOSITA.  
R Antimonii Oxyphururetij 3; Florum Subpur. 3; 
Resinae Russi, Extri. Coni. 4; Suspi. 
Athame s. q. i. in Pilulae xxv, quorum capiat 
ibi etque apud, ter quidem.

Form. 467. PIULAE ANTIMONII ET RUSSI COMPOSITA.  
R Antimonii Oxyphururetij 3; Florum Subpur. 3; 
Extri. Coni. 4; Suspi. Athame s. q. i. in Pilulae 
XXV, quorum capiat binae utque apud, ter quidem.

Form. 468. PIULAE ANTIMONSES.  
R Gum. Ammoniaci 3; Benzoati Pur. 3; 
Myrrhae, Suspi. Athame 3, et que per tres 
die.

Form. 469. PIULAE ANTIMONIDESIBERICI COMPOSITA.  
R Camphoro, Potassa Nitriti, Pur. Digitalis Pur. 3; 
Saponis Composta 3; Extri. Coni. 4; Suspi. 
Simplicee 3, et que per tres die.

Form. 470. PIULAE APERIENTES COMPOSITA.  
R Pilulae, Hydrarg. Pilulae, Aloe cum Myrrha, Suspi. 
Extri. Coni. 4; Suspi. Athame 3, et que per tres 
die.

Form. 471. PIULAE APERIENTES ALTERNAE.  
R Pilulae, Hydrarg., Suspi. Athame 3, et que per tres 
die.

Form. 566. *Pillae Styracis Composita.*

Form. 567. *Pillae Sudorifices.*

B. Hydroargyri Carbonatis (Carbonis) gr. xii.; Antimonii Potosius-Tartari, 3 j.; Olei Crucis in pulv. solutis, gr. vj.; Miscce; tune add. Confect. Fruct. Rosii Canini, q. s. ut rt. massa, in Pilulas x. aquae divid., quarum capiat ii. horam somni.

Form. 568. *Pillae Sudorifices.*

Form. 569. *Pillae Sulphatis Strycninis.*

Form. 570. *Pillae Terebinthina.*

B. Gunni Sicc. 3 j.; Terebinthinae Vulg. 3 j.; Pulv. Glycerbh. q. s. ut fiant Pilulae xxxvi., quarum capiat binas vel tres, ter quotidian.

Form. 571. *Pillae Terebinthinae et Camphorae.*

Form. 572. *Pillae Tonicae Aperienses.*

B. Quinae Sulphatis 3 sa.; 3 j.; Potesia Sulphatis 5 j.; Gummi Stigmatea 3 j.; Masticis g. x.; Pulv. Acacie gr. x.; Olei Juniperi q. s. Tere bened similiter, et divide in Pilulas xxv, quarum semaniatur binas vel tres, bis terque quotidian.

Form. 573. *Pillae Tonicae Aperienses.*

Form. 574. *Pillae Tonicae Aperienses.*

Form. 575. *Pillae Tonicae Aperienses.*

Form. 577. *Pillae Tonicae cum Cupra.*

Form. 578. *Pillae Tonicae cum Sulphate Zinco.*

B. Quinae Sulphatis, Masse Pilulae calaban, Comp. 3 j. 3 sa.; Masse Plutei cum Myrrha 3 j.; Olei Juparii, Sabinii q. s. M. Divide massam in Pilulas xx., quarum capiat binas nocteque.

APPENDIX OF FORMULE.—PULVUL.—PULVIS.

Form. 587. Pulvis Aluminii et Quinque.
B Alumine Sulphatis gr. viii.—xii.; Quina Sulphatis gr.—xii.; Gum. Arab., Saccaria Albi, a gr. xii.; Fiat Pulvis. Dispensa, talee dodecem. Capitam ager tertia quaque horae pulverem unum. (In Adjunctum Fevers, Hematemesis, Paevae Hemorrhagias, &c.)

Form. 588. Pulvis Cepris Amoniaco-Sulphatus cum Zincis.
B Cupri Amonio-Sulphato, Oxidii Zincii, a gr. ss.—i.; Saccaria Albi gr. x.; M. Flat Pulvis. (In Epilepsy et Chorea.)

Form. 599. Pulvis Antimonii et Camphora.
B Antimonii Oxysulphurettii, Radix Paeoniae, a gr. i.—ii.; Camphora ram. gr.—sii.; Saccaria Albi 3j.; M. Flat Pulvis. Dispensa, talee dodece sex; omnium ager altera quaque horae Pulverem unum. (In Chronic Inflammationes of the Respiratory Organs.)

Form. 600. Pulvis Antimonii Compositus.
B Pulvis Antimonii Comp. 3 j.; Antimonii Oxysulphurettii 3 j.; M. Dosis a gr. v. pro statu adulteri.

Form. 602. Pulvis Antiphlogisticus.

Form. 603. Pulvis Antimonialis Compositus.
B Pulveris Antimoniali Comp. 3 j.; Antimonialii Oxysulphurati 3 j.; M. Dosis a gr. v. pro statu adulteri.

Form. 606. Pulvis Antisapmodicus. (Stahlii.)
B Kerossi Mineral. gr.—j.; Potassae Nitritae, Potassae Sulphatis, a gr. x.; Mice bené.

Form. 606. Pulvis Apertius.

Form. 607. Pulvis Belladonnae Compositus.

Form. 608. Pulvis Belladonnae Compositus. (Hecker.)
B Pulv. Rad. Belladonnae gr. i.—iii.; Moschi, Camphora, a gr. v.; Saccaria Albi 3 j.; Tere bene ut dividite in Charlotase viiij. (Antisapmodic, For Pertussis, Ataxia, &c.)

Form. 609. Pulvis Belladonnae Compositus. (Hecker.)
B Pulv. Fol. Belladonnae gr. i.—iii.; Moschi, Camphora, a gr. v.; Saccaria Albi 3 j.; Tere bene ut dividite in Charlotase viiij. (Antisapmodic, For Pertussis, Ataxia, &c.)

Form. 610. Pulvis Belladonnae Compositus. (Osier.)
B Bismuthii Triacet., a gr. ii.; Magnes. Carbon., a gr. v.; M. Flat Pulvis, tertia vel quartae horae simul. (Osier.)

Form. 611. Pulvis Boracis et Sabinis.
B Pulveris Follorum Sabini, Pulv. Zingiberis, 89 j.; Sod. Siboricis 3 j.; Flat Pulvis, bis die simul. (In Amenorrhoea with a languid pulse.)

Form. 612. Pulvis Calceolanae Compositus.
B Hydragryi Chloridi, Saccaria Albi, a gr. j.—ii.; Pulveris Digitalis 3 j.; Mice. Dosis, a gr. j. ad gr. v.

Form. 613. Pulvis Calceolanae Compositus.
APPENDIX OF FORMULÆ.—PULVIS.

Form. 614. Pulvis Campshore.
B. Campshor 3 s. ; Rch. Recife 3 v. ; CTTY. terendo pulv. ; esse ad 3 s. ; Sacchar Purificati 3 s. ; Pulv. Aescl. 3 s. ; M. Fiat Pulvis. In chart. x. utens est distribuendi.

Form. 615. Pulvis Campbelli et Zinci.
B. Camphor 3 s. ; Zinci Oxidi gr. xv. ; P. In Chartulis iv. distribuendo ; quarum sumnat unam horam saepe (in Epilepsy supervenient patientibus, et connected with vincular desesses and indulgences).

Form. 616. Pulvis Carminalis (1).
B. Magnesiac gr. viij. ; Seminum Anidroti cont. ; Seminum Fumiculi cont. ; gr. ij. ; Croci gr. ; Sacchari Albi gr. viij. ; Continua bene simul, et esse Pulvis. Capitam diurnam statim, et alterum post horam. (For the Tormina of infants, &c.)

Form. 617. Pulvis Carminalis (2).
B. Magnesiac; Succ. Albi, s. 3 s. ; Pulv. Cortici Canelle; Sem. Fumic. cont. ; gr. xx. ; Olei Anisii iii. ; Tere bene simul, et dividite in Chartulis vij. quarum capitam unam bis terve quotidiem, vel urgentibus tormentis.

Form. 618. Pulvis Carminalis (3).
B. Sem. Anisi, Sem. Carulli, Sem. Cornelli, Sem. Fumiculi s. ; Cort. Auranti, Rad. Zingib., gr. vi. ; Croci Purificati 3 s. ; M. Mol. 3 s. ; Sacchari Albi 5 s. ; Tere bene simul. Dosis, 3 s. — 5 s.

Form. 619. Pulvis Caltaticus.
B. Hydrargyr Cholorid, Pulveris Camphoris, Pulv. Jalapae, Pulv. Rhei, Pulv. Cinnamoni, s. 3 s. ; M. Disse. Dosis, s. gr. v. ad 3 s.

Form. 620. Pulvis Cinchonae Composita.
B. Pulv. Cinchonae 3 s. ; Pulv. Moschi gr. xx. ; Camphori 3 s. ; Ammonis Sesquichloridi, gr. xx. ; Olei Suavi et Olei Menthei ad 3 s. ; M. Disse, pro parte dividite in Pulv. vij. et ad 3 s. pro parte bis terve die.

Form. 621. Pulvis Cinchonace cum Soda.
B. Pulveris Cinchonae, Soda Carbonatis, ad partes equales. Dosis, ad gr. v. ad 3 ss. bis terve in die.

Form. 622. Pulvis Cortis Cephalic Comp.
B. Pulv. Cortici Cephalici gr. x. ; Pulv. Cinnaminii Comp. gr. v. ; Olei Pini sext. ; M. Pulv. Fitoia, ter in die capienti.

Form. 623. Pulvis Crete et Rhei Compositus.
B. Cretae Preparati 3 s. ; Saponis Asmidii., Pulv. Rhei, ad 3 s. ; Hydargyr cum Cretace 3 s. ; Olei Fumiculi 3 s. ; Sacchari Albi 3 s. ; Tere bene simul. Dosis, 2 s. ad 3 s. pro parte bis terve die. (Pro Infantum Diarrhoea.)

Form. 624. Pulvis Cretece.
B. Cretae Preparatae, Aescini Gummi Ver. pulv. ad 3 s. ; Sacchari Purificati cont. 3 s. ; M. Disse. Dosis. Pt. Pulvis.

Form. 625. Pulvis Cyanidi Zinchi.
B. Zinci Cyanidi gr. viij. ; Magnesiac Calcinitis ad 4 s. ; Pulveris Cinnaminii gr. iv. ; M. Pulv. Fitoia, quarti horae eundo. (In Gastralgia, Dyspepsia.)

Form. 626. Pulvis Diureticus.
B. Gum. Guatari 3 s. ; Florasulphur 3 s. ; Calomelana 3 s. ; Radici Irisis Flor. ; Sem. Fumiculi, ad 3 s. ; Opuli Erot. gr. v. ; Sacchari Albi 3 s. ; Tere bene simul, et dividite in Pulv. vij. et ad 3 s. pro parte bis terve die.

Form. 627. Pulvis Diureticus (1).
B. Potassae Nitriti, Potassae Bitartrati, ad 3 s.; Pulv. Sellei exsiccatus, gr. viij. ; Pulv. Zingiberis gr. v. ; M. Disse. Dosis, et dividite in Chartulis vij. et ad 3 s. pro parte bis terve die.

Form. 628. Pulvis Diureticus (2).
B. Potassae Bitartrati 3 s. ; Pulv. Sellei exsiccatus, gr. iv. ; Pulv. Digitatis gr. v. ; Pulv. Zingiberis gr. v. ; M. Disse. Dosis, et dividite in Chartulis vij. et ad 3 s. pro parte bis terve die.

Form. 629. Pulvis Eacropoetica.
B. Potassae Bitartrati, 3 s. ; Magnesia Carbonat. ; Florasulphur, ad 3 s. ; Potassae Nitriti, 3 s. ; M. Disse. et dividite in Chartulis vij. et ad 3 s. pro parte bis terve die.

Form. 630. Pulvis Eacropoetica (1).
B. Potassae Bitartrati, 3 s. ; Sodii Biphosphatis, ; Magnesia Carbonat. ; ad 3 s. ; Pulv. Rhei, Flor. Anthemi, ; Pulv. Sem. Fumiculi, ad 3 s. ; Sacchari Albi 3 s. ; Olei Juniperi et Olei Anisii ad 3 xiv. ; Tere bene simul. Dosis, 3 s. — 5 s. bis terve quotidie.

Form. 631. Pulvis Eacropoetica (2).
B. Magnesia Carbonat. ; Potassae Bitartrati, ; Sulphuris Sublimatis, ; Pulv. Rhei, Pulv. Flor. Anthemi, ; Pulv. Sem. Fumiculi (vel potius Sacchari Albi 3 s. ; Olei Fumiculi Dul. et Multa, 3 s. ; Olei Juniperi m. viij. ; Tere bene simul. Dosis, 3 s. — 5 s. bis terve quotidie ex vehiculo quovis idoneo. (In Oedem, Jaundice, &c.)

Form. 632. Pulvis Excipiens.
B. Biphosphatis Sodii gr. xx. — 3 s. ; Pulv. Sabini gr. v. ; Pulv. Calcret. ; Pulv. Rhei, Pulv. Zingiberis, gr. xv. ; Dis. 3 ss. ; M. Disse. Dosis, 3 s. — 5 s. bis terve quotidie, et dividite in Chartulis vij. et ad 3 s. pro parte bis terve die.

Form. 633. Pulvis Infantis.
B. Rhei Radices Pulveris 3 s. ; Magnesia Carbonatis 3 s. ; Zingiberis 3 s. ; M. Disse. Dosis, 3 s. — 5 s. bis terve quotidie, et dividite in Chartulis vij. et ad 3 s. pro parte bis terve die.

Form. 634. Pulvis Ipecacuanhae cum Cinnamoni.
B. Hydrargyr Cholorid, Pulveris Camphoris, Pulv. Jalapae, Pulv. Cinnaminii, 3 s. ; M. Disse. Dosis, 3 s. — 5 s. bis terve quotidie.

Form. 635. Pulvis Jalape Compositus.
B. Jalape Radichi Pulveris 3 s. ; Potassae Bitartrati 3 s. ; Capaci Baccarum Pulv. Gr. xii. ; Camomia, secundum, permisce. Dosis, 3 s. ad 5 s. m. sequens.

Form. 636. Pulvis Jalape et Calomelana.
B. Pulv. Rad. Jalape gr. xx. — 3 s. ; Hydargyr Cholorid gr. v. ; Tere probe cum Sacchari Albi 3 s. ; et ad 3 s. ; Pulv. Aescini 9 s. ; Olei Cuminum m. ; M. Fitoia, statim sequens.

Form. 637. Pulvis Kerami Mineralis.
(Hydrargyrum Sulphuris Antimonii. DESMELLEN.)
B. Aqnae Ploviae, part. 200 ; Carbon. Socia part. 179. ; Sesquialbumi Antimoni pulv. part. 6. Dissolve the Soda in the water whilst boiling, and add the Sulphate in the solution for half an hour, stirring it frequently. Filter the boiling liquid in a vessel containing warm water which had been previously boiled. Decant the water after it is cooled. Wash the precipitate of iron sulphate with water, treat with cold water, afterwards with warm water, until it passes off quite dissolved. Lastly, press it, and dry it in the shade. (Stimulant, Emetic, Diaphoretic, Alterative, Nosecle, Expectorant. Dose 3 — 4 gr. v.)

Form. 638. Pulvis Kerami Mineralis et Campshor.
B. Kerami Mineral. gr. vi. ; Campshor subject. in Pulv. gr. vi. ; Potassae Nitriti gr. v. — m. ; M. Fitoia, pro una dose.

Form. 639. Pulvis Kerami Mineralis Camphoratus.
B. Kerami Mineral. gr. vi. ; Campshor pulverizatus gr. viii. ; Potassae Nitriti gr. xiv. ; Sacchari Albi 3 s. ; Tere bene simul, et dividite in Pulv. Fitoia, statim sequens, quater in die.

Form. 640. Pulvis Lentiocoeus Hyperochromicus.
(KLEEM.)
B. Fleredina Cort. Aurant. Pulv. Radici Rhei, Pulv. Tarrattis, ad 5 s. ; Olei Cajuiputi m. ; M. Fitoia, pro una dose.

Form. 641. Pulvis Lenticularis.
B. Pulveris Traegetheirii Comp. Pulv. Rhei, et 3 s. ; Pulv. Ipecacuanhae Comp. 3 s. ; Hydargyrum cum Cretaz, 3 s. ; M. Disse. Dosis, 3 s. — 5 s. bis terve quotidie, et dividite in Chartulis vij. et ad 3 s. pro parte bis terve die.

a I have given the directions for that preparation, and a few others, in English, to prevent any mistake occurring in respect of them.
APPENDIX OF FORMULÆ. — PULVIS — SOLUTIO. xxiii

Form. 622. Pulvis Nitro-Opisthus Ipecacuanhae, vel Pulvis Dobyel.
B. Ipecacuanhae radixes centum 5; Opium Cruci-
ctis gr. xiv; Potassii Nitrat. 5 viii. et gr. xv. Tere simili, et fit Pulvis. (A scrupul of this powder contains one grain and a half of opium, two grains of ipecacuanha, and sixteen grains and a half of nitrate of potass.)

Form. 643. Pulvis Pergonis.

Form. 644. Pulvis Refregiers. (1.)

APPENDIX OF FORMULÆ. — SOLITUO — TINCTURA.

FORM. 674. SOLUTIO MORPHII HYDROCHLORATIS.
B. Morphium Hydrochlorat. gr. x.; Aq. Destillat. Calid. M. 1000. Solve. (Dose twenty-five minims — equal to 1 gr. of the Hydrochlorate.)

FORM. 675. SOLUTIO MORPHII SULPHATIS.
B. Sulphatis Morphini Ver. gr. iv.; Aq. Destillat. 3i.; Solve. (Of the same strength as Laudanum.)

FORM. 676. SPIRITUS ETHIRIS HYDROCIRULICI.
(Ollis, Spiritus Fodoricum Civitatis.)
B. Acidi Sulphoricæ II. ij.; Spiritus Rectificat. cong. Distributur liquorum, secondum artem.

FORM. 677. SPIRITUS AMMONII ABSINTII.

FORM. 678. SPIRITUS CASTORII AMMONIATUS.

FORM. 679. SPIRITUS CASTORII COMPL.

FORM. 680. SPIRITUS TEREBINTHINATUS.
B. Olei Terebinthinæ 3j.; Spirit. Vini Rect. 3vij. Diffusil lienis cum calore. Dosis. 7ij. viij.—x. (In Jaundice.)

FORM. 681. SPIRITUS TEREBINTHINATUS COMPL.

FORM. 682. SUPPOSITORII PLUMMI COMPOSITI.

FORM. 683. SYRUPUS BELLADONNAE.

FORM. 684. SYRUPUS MORPHII ACETATIS.
B. Morphiae Acetatis gr. iv.; Syrupi Clarificati 3jv. Mice ut fiat Syrupus. (In doses of from two teaspoonsful to a tablespoonful, three hours, or only at bed-time.)

FORM. 685. SYRUPUS MORPHII SULPHATIS.
B. Morphiae Sulphatis gr. iv.; Syrupi Clarificati 3jv. Mice. (In the same doses as the Acetate. May be given alternately with the Acetate.)

FORM. 686. SYRUPUS PAPAVERI.

FORM. 687. SYRUPUS POTAOSI SULPHURÆ.

FORM. 688. SYRUPUS QUINCEI.
B. Syrupi Simplex 3vii.; Quinque Sulphatis gr. xxxii. Caput Cochlear. 3ij. minima, bis ter de ele.

FORM. 689. SYRUPUS RHEII COMPOSITUS.

FORM. 690. SYRUPUS SENNAE ET MAHASS.

FORM. 691. SYRUPUS SULPHURESI SODII.
B. Soda Pura (cum Alcoh. prepar.) 2j.; Aq. Destillat. 3v.; Liquore lenis ingui, et addit Sulphurus Puri quantum solvi potest.

FORM. 692. LIPUSIS CONTR. 3j.; Syrupi Communis 3xxx. Mice benen in vase bene obtortuo. (Doses of 3j.—3j. for infants, 3ij.—3ij. for adults.)

FORM. 693. TINCTURA ACETATIS FERRI COMP.

FORM. 694. TINCTURA ACETATIS MORPHII COMP.

FORM. 695. TINCTURA ETHIRIS VALERIANE.
B. Radicii Valerianæ 3ij.; Saponis 2j.; Aetherei Sulphurii non-rectificat. 3v.; Alcoh. Rectifi. 3ij. Macearum per triduum et ista.

FORM. 696. TINCTURA ALCEA ALKALIS. (SAXON PR.)

FORM. 697. TINCTURA ALBAE POTALIS.
B. Potassae Hydrates 3ss.; Alcoholis Consecrat. 3iv. Macear per dies septem in balneo arenae.

FORM. 698. TINCTURA ALKALINAE STIBIATI.
B. Antimundi Crud. 3i.; Potassae Carbon. 3ss.; Sulfuris, quod sepultum in a crucibile, et reducent to yellowish soccor; tamen poterit immediatim in fallacem mortem, et pour upon them rectifit Alcoholic 3ij. Macerate for three days, et filter.

FORM. 699. TINCTURA AMARAE.

FORM. 700. TINCTURA AMMONIACI ALKALINAE.
B. Cammi Ammoniaci 3ij.; Liq. Potassae Carbon. 3ij.; Myrrhi 3ij.; Alcoh. 3ij.; Macear per dies septem, et cola. Dosis. 3ss.—3jss.

FORM. 701. TINCTURA BALSAMICA. (1.)
B. Olei Terebinthinae 3ij.; Tinct. Myrrhi 3ij.; Tinct. Benzoini Comp. 3iv. Macear in loco calido. (Internally, and to Indolent Sores, &c.)

FORM. 702. TINCTURA BALSAMICA. (2.)
APPENDIX OF FORMULÆ. — TINCTURA.

**Form. 701. Tinctura Balsami Toluii.**

**Form. 704. Tinctura Belladonnae.**
B. Belladonnae foliorum exsiccatorum 3 l.; Spiritus Tenoris 0 j.; Macera per diem quaeriturdecem et colat.

**Form. 705. Tinctura Benigna Ammonia.**

**Form. 706. Tinctura Bruci.**
B. Brodi Puræ gr. x.; Alcoholis (q. e. 872). 3 j.; Solve (3 j. contain. gr. jas. of Bruci. Dose 3 ss.—3 j.)

**Form. 707. Tinctura Calami.**
B. Calami Radices contus 3 l.; Spiritus Tenoris 0 j.; Macera per diem quaeriturdecem et chartam colat. (Dosis. 708. Tinctura Camphorae Thabaeae.)

**Form. 709. Tinctura Camphorae.**
B. Camphorae conf. 3 l.; Spirit. Vini Teu. 0 j.; Macera bened. et colat. (Dosis. 3 j.—3 j.)

**Form. 710. Tinctura Cascariibü Alkalina.**
B. Corticii Cascarii conf. 3 ss.; Potass. Carbon. 3 j.; Spirit. Teu. 0 j.; Macera bened. et colat. (Dosis. 3 j.—3 j.)

**Form. 711. Tinctura Castorei Alkalina.**
B. Castorei contus 3 j.; Potass. Carbon. 3 j.; Croci Sigill., 3 j.; Spirit. Hortamelian. 3 j.; Macera per triennium et colat. (M. Dosis, 5 ss.—5 j.)

**Form. 712. Tinctura Centaurii Cicumin.**
B. Centaurii Cicumin. (Browning tops of Centaurii.) 3 l.; Spiritus Tenoris 0 j.; Macera per diem quaeriturdecem et colat. (Dosis 3 j.—3 j.)

**Form. 713. Tinctura Cinchonae Sulphatis.**
B. Cinchoni Sulphatis gr. XXXV.; Alcoholis Rect. 3 j.; Solve (Dosis. 3 j.—3 j.)

**Form. 714. Tinctura Conii.**
B. Conii foliorum exsiccatorum 3 l.; Cardamomi Semen contusorum 3 l.; Spiritus Tenoris 0 j.; Macera per die quaerit et chartam colat. (Dosis. 715. Tinctura Digitalis Athereae.**
B. Foli. Digitalis exsic. et pulv. part. 1.; Ether. Subph. 3 j.; Spirit. Macera per triennium et colat. (Dosis. 3 j.—3 j.)

**Form. 716. Tinctura Dioscoree.**
B. Foli. Dioscoreae contus 3 j.; Spirit. Teu. 0 j.; Macera per diem septem et colat. (Dosis 3 j.—3 j.)

**Form. 717. Tinctura Dipsica.**
B. Olei Juniperi 3 ss.; Spirit. Etheris Nitrid. Tinctura Digitalis Athereae, 3 j.; (Dosis. SS. —3 j.) ter quartam die in die. Hufeland.)

**Form. 718. Tinctura Ferri Athereae.**
B. Acid. Hydrochlorici 3 j.; Acid. Nitridi Dilut. 3 j.; Ferti Linament. q.; Solve. Dissolve the iron in the acid; evaporate to dryness; afterwards deliquesce the residue by exposure to the air, and mix the deliquesced liquor with double its weight of Sulphuric Ether, allowing the mixture gently until it assumes a golden yellow colour: then decant, and add double the quantity of rectified Alcohol. This Tincture may be used previously to the addition of the Alcohol, or subsequently. In the state of Ether the dose is from 20 to 30 drops; in that of Etherised Tincture, from 20 to 30 drops. It is useful in Diseases of Debility, and in Spasmodic Affections.

**Form. 719. Tinctura Fructu Vanillae.**
B. Fructus Vanillae concis. et contus. part. 1.; Alcoholis part. 1.; Macera lenum calore per die octo, et colat. (Nervina, Analgesia, Excitant, &c. STAFF.)

**Form. 720. Tinctura Gallaris Composita.**
B. Gallarii Seminis 3 j.; Pimentae fructus contus. 3 j.; Cardamomi Seminis contus. 3 ss.; Spirit. Rectificat. Oj.; Aqua Destill. 0 ss.; Macera per diem quaeriturdecem et colat.

**Form. 721. Tinctura Gallici.**
B. Gallarii contus. 3 l.; Spirit. Tenoris 0 j.; Macera per die octo, et per chartam colat. (Dosis. 722. Tinctura Iodimi Fortiori.**
B. Iodini gr. 3 j.; Spirit. Rectificat. 3 j.; Solve, terendo in vaso vitreo. (3 j. contain. five grains of Iodine.)

**Form. 723. Tinctura Iodimi Minor.**
B. Iodini gr. 3 j.; Spirit. Rectificat. 3 j.; Solve, terendo in vaso vitreo. (M. 3 j. contain. gr. jas. of Iodine.)

**Form. 724. Tinctura Lobelliae Inflatae.**
B. Herb. Lobelliae Inflatae exsic. 3 j.; Spirit. Vini Teu. 0 j.; Macera lenum calore per die octo, et colat. (Emetic in doses of 3 j. to 5 j.; Anti-aspasmodes in doses of 3 j. 2 to 3 j.; and Diuretic in smaller quantities.)

**Form. 725. Tinctura Myrhis Alkalina.**

**Form. 726. Tinctura Nervosa.**

**Form. 727. Tinctura Nuci Vomicae.**
B. Extr. Nuci Vomicae exsic. gr. iv.; Alcoholis (36% J.; Solve. (3 j. Tincture ad gr. iv. Extr.)

**Form. 728. Tinctura Opis Camphorata.**
(Sive Elixir Purgericum Pharm. Pristis.)

**Form. 729. Tinctura Opii Composita.**
(Pot Laudanum Liquidum Fumum Sphagnieli.)

**Form. 730. Tinctura Phellandrii.**
B. Sem. Phellandrii Aq. 3 ss.; Alcoholis 5 j.; Macera per horas xxiv. et adde Vini Burgundiae 3 j.; Macera per diem tres, et colat. Capiat M. X.—X. (In Chronic Bronchial and Pulmonary Affections.)

**Form. 731. Tinctura Quinque Sulphatis.**
B. Quinque Sulphatis gr. VIII.; Spirit. Vini 3 j.; M. Flat Tinctura.

**Form. 732. Tinctura Quinque Sulphatis Acid.**
B. Quinque Sulphatis gr. xiv.; Tinctura Aurantiæ Comp. 3 ss.; Acid. Sulphuratus Dilut. 3 j.; M. Flat Tinctura. (Dosis 3 ss.—3 j.)

**Form. 733. Tinctura Rhantian.**
B. Krameris Radices contus. 3 j.; Spiritus Tenoris 0 j.; Macera lenum calore per die octo, et per chartam colat. (This Tincture is strongly impregnated with the medicinal virtues of the root. It is a very grateful tonic, when given according to the following formula —)

APPENDIX DE FORMULÆ.—TINCTURA—UNGENTUM.

Form. 734. TINCTURA RHATANIS AROMATICA.

B. Krameris Radicis continuae 3 lb.; Canellae Cortexis continuae 3 lb.; Spiritus Tincturæ O. J lyricæ per due dies ad quartam tardam, et per chartam cala.

The following is an agreeable method of exhibiting this tincture:—

Infus Aurantii Compositi 3 j.; Tincturæ Rhataniae Aurantii, Myrcii Zizugeriae, ad j. Masse. Fiset. Mistura; cumus suscit cohet. ampla ill. ter in die, urgeante Laudroni vel Parum. (Speargr.)

Form. 735. TINCTURA REALIS ANNAEA.

B. Radicis Rhodi concedes, Radicis Glicyrrhizae conce. ad 3 lb.; Seminum Aniis concus. Sacchari Purificati, ad j.; Spiritus Terni Topiis octoros ill. Masse per dies quaetenecdecim, et cala.

Form. 736. TINCTURA RHODI.

B. Rhodi Liquid ras. 3 lb.; Spiritus Rectificati O. J. Masse per dies quaetenecdecim, et per chartam cala.

Form. 737. TINCTURA SABINE ALKALINA.

Form. 738. TINCTURA SENO AMARA.

Form. 739. TINCTURA STRAMONII.

B. Drynaria Stramonii Simul semis. 3 lb.; Spiritus Terni Topiis ill. Masse per dies quaetenecdecim, et cala.

Form. 740. TINCTURA SYNTechNÆ.

INDEX.

Fluids, the circulating, contamination of 961-969

Fever, diagnosis of their several states 929, 930

--- their connection with epidemic and endemic diseases 928, 930

--- their connection with erysipelas 928, 930

--- infections, nature of 928-930

--- author's inference as to the prevention of 928, 930

--- pathological inference respecting 932

--- literary notices of 939-950

--- period of commencement 919, 920

--- periods of occurrence from parturition 932

--- prognosis of their different forms 931, 2

--- synonyms and definitions of 949

--- treatment of 933-940

--- their types and forms described 931, 2

Fever, putrid-amydemic, treatment of, in 1,1024-1,1025

--- treatment of their complications 1,1027

Fever, remittent, Biblog. and Refer. 961

--- treatment of their modifications 1,1025

--- defined 946

--- See also Remittent

Filiform tissue, alterations of 1,1044

--- Biblog. and Refer. 1,1044

--- inflammation of 1,1043

Filaments and fibres of morbid muscular and nervous tissue 700

Filaria, systematic description of 1,1002

Filaria Medinensis, history and localities of 1,1003

--- rigorous treatment, curative of 1,1417

--- symptoms and diagnosis of 1,1004

--- systematic description of 1,1401

--- synonyms of 1,1004

--- treatment of 1,1017

--- fingers and nails, alterations of, in 1,1012

--- and nails, signs of disease furnished by 976

--- Fish-disease in kids 976

--- Fish poisons, sources of 985

--- symptoms of 985

--- treatment of 985-988

--- Fish-skin disease. See also Ichthyosis

--- Ichthyosis, gastro-collic, diagnosis of 1,312

--- gastro-intestinal, diagnosis of 1,1309

--- Ichthyosis in ano, described 989

--- Ichthyoses, chronic 1,1118

--- Ichthyosis, renal, remarks on 1,1054

--- Flexibility of soft solids as a sign of disease 973

--- Flatalence in connection with digestion 1,331

--- Flatus, description by 977

--- of bowel, treatment of 1,1044

--- definition of 1,1044

--- of the intestines, symptoms and effects of 969

--- of the stomach, causes and phenomena of 1,1045

--- as a symptom 969

--- of stomach, treatment of 1,1047

--- symptoms of disorders consequent on 1,1045, 9 treated by 1,1047

--- Flexion of the uteri 1,338

--- Flexions of the uterus 1,358

--- treatment of 1,270

--- Floating, during delivery, external 1,112

--- during labor, treatment of 1,250

--- treatment subsequently to 1,117

--- after delivery, treatment of 1,116

Fluid, the cerebral spinal, in connection with palsy 36

--- fluids, the circulating, contamination of 961-969

--- in dropsy, characters of 1,605

--- Fucus, Biblog. and Refer. to diseases of 1,1019

--- death of the causes of 1,1018

--- death of, from syphilis 1,1019

--- diseases causing death of 1,1048

--- diseases observed in the 819

--- in the 1,1343, 4

--- syphilis, infected from one or both parents 1,1343, 4

--- Fomentum Cauphoratum 1,137, Ap. 6

--- Food, changes in the blood produced by 1,1469

--- in fever, desire of, &c. as a sign of disease 985, 9

--- of man in relation to climate 1,1345

--- in respect of the varieties of the species of 1,1345

--- its influence in disposing to phthisis 1,1322

--- Gastroenteritis of the parents may cause scrofula in the offspring 735

--- and drink, as causing disease 1,1045

--- of the young in relation to scrofula 1,137, 8

--- poisons, symptoms and treatment of 975, 8

--- Foul-mouthed, disease by poisoning by 431

--- Formative period in infectious diseases 933, 4

--- Formations, parasitical and others may be thrown off by producing organic, nervous, and vital power 1,1043

--- Forms and modifications of phthisis 1,1092-7

--- Fotus Conili 1,704, Ap. 58

--- Fragility of bones 1,922

INDEX.

Heart, alterations of its consist.-
cous diseases valv.-
- treatment of - ii, 215
atrophy of the - ii, 216
its causes - ii, 216
its symptoms and treat- ment of - ii, 216
carcinoma, &c., in the contractions of the cavities - ii, 220
and orifices of - ii, 204
treatment of - ii, 216
cysts and hydatids in the dilatation of its cavities - ii, 216
treatment of its orifices - ii, 220
treatment of - ii, 212
- causes producing dilata- tion of the cavities and orifices of - ii, 211
- signs and symptoms of ii, 215
- progression, termination, and prognosis of - ii, 212
- lesions of the orifices of ii, 183
- lesions producing rupture of the lesions of the valves of the ii, 176
- local signs of its diseases - ii, 170
- intimate nature of its les- sions - ii, 170
- nature of its diseases - ii, 171
- states of, afflicting the pulse 542
- morbid symptoms of - 947
- pathological cause of diseases - ii, 169
- prognosis of its diseases - ii, 173
- seat and anatomical charac- teristics of its diseases - ii, 170
- of the natural sounds of the - ii, 166
- of the morbid sounds of the - ii, 167
- structure of the - ii, 165
- structural lesions of the, de- scribed treatment of - ii, 202
- symptoms and signs fur- nished by - ii, 176
- general symptoms of its dis- eases - ii, 170
- symptoms of disease of the valves of - ii, 183
- treatment of its diseases ii, 173
- treatment of organic dis- eases of - ii, 174
- general view of diseases of the - ii, 169
- increased action of the. See also Palpitation - ii, 179
- impaired action of the - ii, 174
- treatment of - ii, 175
- irregular action of the - ii, 175
- treatment of dilatation of the cavities and orifices of, when caused by dis- eased valves of ii, 213
- causes of ii, 230
- endocarditis, treatment of ii, 198
- fatty degeneration of, signs and symptoms of - ii, 216
treatment of - ii, 217
- rigourous constrictions in the cavities of the - ii, 201
- blood in the - ii, 220
- from morbid matters in the - ii, 225
- from malignant formations in the - ii, 219
- functional disorders of the - ii, 220
- gangrene of the - ii, 227
- hyper trophy of the - ii, 227
- description of ii, 202
- nature and causes of ii, 203
- disease complications of - ii, 203
- diagnosis and symp- toms of their diseases ii, 267
- influence of, on the ce- reral circulation ii, 205
- prognosis and termina- tions of ii, 200
- treatment of ii, 201
- treatment of ii, 209

INDEX.

Heart, treatment of hypertension from disease valv.-
- treatment of - ii, 215
- induration of - ii, 215
- indurations, cartilaginous, and on its characters of ii, 193
- induration of blood in the structure of - ii, 216
- of serum in the structure of - ii, 216
- inflammations of the. See also Carditis ii, 179
- excitation of - ii, 207
- exciting causes of - ii, 207
- predisposing causes of ii, 193
- inflammation of, in chil- dren - ii, 200
- complications of its inflam- mations - ii, 196
- diagnosis of inflammations of ii, 196
- inflammations of, duration and termination ii, 197
- inflammations of the endo- cardiitis. See also Endocar- ditis ii, 190
- inflammations of, their causes - ii, 197
- their relapses ii, 190
- treatment of inflamma- tions of ii, 193
- pathomorphology of inflammatory charac- teristics of the - ii, 173
- of inflammations in children - ii, 201
- neurotic or painful affec- tions of ii, 178
- causes of ii, 178
- diagnosis of ii, 178
- obesity of ii, 216
- treatment of ii, 217
- edema of, described ii, 216
- oedematosous and cartilaginous formations in ii, 243
- palpitations of, after parturition ii, 495
- during pregnancy ii, 495
- percussion of the region of the - ii, 188
- perforation of one of its cavities of ii, 153
- numerous formations in - ii, 220
- ruptures of the - ii, 223
- ruptures of the valvules of ii, 224
- symptoms and diagnosis of ii, 224
- partial ruptures of ii, 223
- inflammatory softening of ii, 192
- different kinds of softening of ii, 192
- symptoms of inflammatory softening of ii, 194
- non-inflammatory or chronic softening of ii, 215
- symptoms of ii, 215
- tubercles in the ii, 218
- tumours of various kinds in ii, 219
- ulceration of the ii, 193
- unnatural positions of ii, 226

- - discharges from the vagina occurring 450
- - treatment of 450
- diseases incident to, Bibl. and Refer to 457
- disorders incident to 448
- hysterial during 451
- - treatment of 452
- disorders of, on the course and treatment of acute diseases 458
- inflammation of the cervix uteri during 1248
- vagus during 511
- disorders of the nervous system during 434
- affections of the sexual organs caused by 449
- treatment of 449
- small-pox during 819
- state of the female at the end of the full period 482
- sympathetic affections during 439-6
- - spasm, pain, &c., of the uterus during 450
- - treatment of 451
- and purulent states as predisposing to disease 1461
Preeclampsia of position of gestation, &c., means of 232
- Principles of the therapeutics 1637, 8
- principles, general of therapeutics 1637-41
- special therapeutics 1641-50
- Principles of moral phenomena described 1584
- Proctidens uteri, described 1588
- treatment of 1589
- Proctitis, causes of 598
- forms of, described 598, 3
- symptoms of 599
- treatment of its several forms 599
- Proctitis, acute, described 598
- - terminations of 599
- - acute, history of 553
- chronic and sub-acute 592
- terminations of 553
Practic, syphilitic and gonorrheal 553
- causes of 558
- Productions and secretions attendant upon the economy 1288
- Professions and employments as predisposing to insanity 1788, 4
- Prognosis of disease, causes of 595-1008
- Prognostic symptoms in continued fever 1583, 4
- Prophylaxis of the uterus, described 1235
- Prostration, lateral, of the ribs 1311
- Protests of the infectious nature of purulent fevers 566
- - of the pelvis
- Prophylaxis diffuse, described 548
- gout, described 548
- in the abdomen, described 548
- - treatment of 548
- Puerperal, mercurial, diagnosis of 461
- Puerperal convulsions, described 427
- - treatment of 427
- Puerperal fever, causes of puerperal fever, described 427
- - diagnosis of 428
- - treatment of 428
- - - described previously 428
- Puerperal fevers, morbid phenomena of 429
- - individual measures for 431
- Proximate cause of fever, author's views as to 1456
- Prophylaxis of disease, &c., means of 232
- Proximity of position, a cause of fever 945
- - of 946
- - definition and synonyms 946
- - description of its forms 946
- - diagnosis, local forms of 946
- - diagnosis of 946
- - treatment of 946
- - - of its varieties 946
- - - diagnosis of 946
- - forms and states of 946
- - treatment of 946
- - of the virulence, described 946
- - - treatment of 946
- Prussic acid, poisoning by symptoms of 397
- - diagnosis of 397
- - modus operandi of 397
- - period of death from 397
- - - appearances after death from 397
- - - relation between its effects and the quantity of the poison 397
- - - quantity of phial requisite to destroy life 397
- - and its compounds, treatment of poisoning by 397
- - Pseudo-hydatid or vesicles, described 114, 264
- - Pseudo-hydatid, described 114
- - - treatment of 114
- - Pseudomes, inflammation and suppression of. See Pseudo, mat, Bibl. and Refer to 114

- variety of from the Cape of Good Hope - 1391
- Tenia nana, description of - 1391
- serrata, noticed - 1384
- Tenia solium, description of the common variety of the brood of, contained in its eggs, carried by - 1339, 50
- description of - 1389
- systematic description of stages of its development - 1388
- the mature state of, described - 1389
- synonymy of - 1384
- Tape-worm colony, or struila described - 1396
- Tape-worms, treatment of. See also Tauria - 1366-17
- described. See also Tauria - 1366, 17
- development of - 1383-4
- generation and growth of - 1383, 3
- of their treatment - 1408-16
- Tartar-enameled, poisoning by - 1349
- Taste, symptoms furnished by - 1348-13
- Taxus lucida, poisoning by - 1348-13
- Teeth, signs of disease furnished by - 1348-13
- Teething, symptoms of - 1348-13
- Temperature and diathesis, as predisposing to dysentery - 1356
- to insanity - 1348-13
- affecting the pulse - 1348-13
- Temperature, as predisposing to disease - 1348-13
- very high, as a disfavour to - 1348-13
- of resired air, as a sign of disease - 1348-13
- of the surface of the body in - 1348-13
- of analyzed parts - 1348-13
- and humidity of climates - 1348-13
- cause diseases - 1348-13
- Tenderness, as a symptom of disease - 1348-13
- Tastes, syphilitic affections of the - 1333
- rheumatism of the - 1332
- Tetanus, appearances after death from - 1348-13
- in the spinal chord in fatal - 1348-13
- exciting causes of - 1348-13
- predisposing causes of - 1348-13
- of the cerebro-spinal system and membranes in - 1348-13
- description of - 1348-13
- diagnosis of - 1348-13
- from spinal marasmus - 1348
- from infantilism - 1348
- from rickets - 1348
- of the ganglia and sympathetic nerves in - 1348
- duration of - 1348
- states of injuries caused by - 1348
- external means of treating - 1348-13
- of various internal means for - 1348-13
- of various external means for - 1348-13
- internal and constitutional means of treatment of - 1348-13
- of successive and combined means - 1348-13
- pathological inferences and results respecting - 1348
- period between the infliction of its cause, and appearance of its symptoms - 1348
- from the belly - 1348
- of sedatives, narcotics, &c. - 1348
- the symptoms described - 1348-13
- from - 1348-13
- local - 1348, 6
- author's prophylactic measures - 1348
- Tenuus, acute, described - 1091, 13
- see also Worms. - 1091, 13
- symptoms of, described - 1093
- spasms of, described - 1093
- the symptoms discussed - 1093
